15th	,,	Friday	,,	X.—Inorganic Chemistry.
19th	,,	Tuesday	,,	XVI. and XVII.—Biology.
20th	,,	Wednesday	,,	XIX.—Metallurgy. XV.—Botany.
21st	,,	Thursday	,,	XIII.—Mineralogy.
22nd	,,	Friday	,,	XXI.—Nautical Astronomy. XI.—Organic Chemistry. XXII.—Steam.

Candidates who do not belong to any regularly constituted Science or Art Class should apply before March 25 to the Local Secretary of the district, or, in case they do not reside within a Special Local Secretary's district, to the Secretar nearest Class which is to be examined in the subject they require. A fee for each candidate, not exceeding 2s. 6d. per may be charged by the Local Committee, or the Special Local Secretary. The Special Local Secretaries for the London are as follows:—Chelsea (East) and Westminster, J. R. Langler, Esq., 130, Horseferry Road, Westminster, S.W.; Cl and Hackney, A. Lovell, Esq., 14, Brampton Road, Cassland Road, South Hackney, E.; City (West) and Finsbury, W Esq., 210, Goswell Road, E.C.; Greenwich and Deptford, J. J. Pakes, Esq., 10, Malpas Road, Brockley, S.E.; Lambe F. Dugard, Esq., 3, Sibella Road, Clapham, S.W.; Lambeth (West), F. Dugard, Esq., 3, Sibella Road, Clapham, S.W. lebone, F. Pope, Esq., 18, Baker Street, Portman Square, W.; Southwark and Lambeth (North), A. Bourne, Esq., Fo Foreign School Society, Boro' Road, S.E.; Tower Hamlets, E. J. Sharpe, Jun., Esq., 28, Oriental Street, East India R Woolwich and Plumstead, R. T. Smith, Esq., 246, Burrage Road, Plumstead.

Individual candidates who do not reside near any place where a Special Local Secretary has been appointed, o Examination Committee formed, may be examined in Second Grade Drawing and in Science at the South Kensington Mu for as room will allow, on payment of a registration fee of 2s. 6d., if application be made on Form No. 325 before April 5s. afterwards up to April 25, for each evening on which they wish to be examined, or a composition fee of 10s. for an of evenings. Applications for examination at South Kensington cannot be received after April 25. Schools and Class be examined at South Kensington.

By order of the
Committee of Council on Education.

CITY and GUILDS of LONDON STITUTE for the ADVANCEMENT of TECHNICAL EDUCATION.

COMMITTEE of the INSTITUTE are prepared to appoint a ESSOR of CHEMISTRY at the FINSBURY TECHNICAL EGE. The Professor will be required to attend at the College during urs prescribed by the Committee, and will be restricted from taking her teaching work or any work which may be considered by the Com- to be inconsistent with his duties at the College. The Salary offered s a year.

ications, addressed to the PRINCIPAL, Finsbury Technical College, uncle Row, London, E.C., to be sent in not later than Saturday, 24.

SOCIETY OF ARTS.

e Meeting on WEDNESDAY, March 25, a Paper will be read by J. ELLIS on "The Musical Scales of Various Nations." Chair will be taken at 8 o'clock by Sir Frederick Abel, D.C.L., C.B.,

H. TRUEMAN WOOD, Secretary.

ty's House, John Street, Adelphi, W.C.

YAL AGRICULTURAL SOCIETY OF ENGLAND.

AGRICULTURAL EDUCATION.

Examination of Candidates for the Society's Senior Prizes and Cer- will take place in the week commencing TUESDAY, May 12, 1885. of the Regulations and of the Form of Entry (which is required to in by April 21, 1885) may be had on application to

MUTUAL LIFE ASSURANCE.

SCOTTISH PROVIDENT INSTITUTION.

EDINBURGH—6, ST. ANDREW SQUARE. LONDON OFFICE—17, KING WILLIAM STREET, E.C.

The ATTENTION of ASSURERS is directed to the SPECIAL ADVANTAGES obtainable in this Society, in respect of ECONOMY—EQUITY—SAFETY.

ECONOMY.—The Premiums are, in many cases, 20 to 25 per cent. under the usual rates, so that a Policy for £1200 o £1250 may generally be had for the yearly payment which would elsewhere assure £1000 only.

EQUITY.—The whole Surplus is divisible among the Policy-holders themselves, on an equitable principle—no share bein given to those by whose early death there is a *loss* to the other Members. From this source large additions have been made, an may be expected in the future.

SAFETY.—The Business (which for ten years has exceeded a Million yearly) is of the most select character, and co ducted at the smallest cost.

The expenses, which are less than in any Office transacting so large a business, were last year under 9 per cent. of the n Premiums, and little over 6 per cent. of the year's Income.

THE FUNDS accumulated from Premiums exceed **£5,000,000**, the increase last year being **£333,383**.

Only two Offices in the Kingdom (both older) have as large a Fund.

Claims under Policies now payable a Month after Proof.

Reports, with Tables of Premiums, &c., on Application.

HE DEBATE ON VIVISECTION AT OXFORD

N our last issue we gave a brief notice of the proceed-
ings in an overflowing Convocation at Oxford, which
ulted in a majority of 412 votes to 244 in favour of the
:ree promulgated by the Hebdomadal Council. This
:ree had only an indirect bearing upon the question of
isection; but as it was made an occasion for a fresh,
d, let us hope, a final trial of strength between the
entific and anti-scientific forces of the University, it is
irable to furnish our readers with a somewhat more
account of what took place than we had time to print
week. Seeing that the debate had clearly been
anised with no small amount of care on the side of the
i-vivisectionists, and that the ablest as well as the
st authoritative speakers in Oxford who could support
ir cause were put forward, we may regard the argu-
nts which were adduced as a fair example of the best
t can be said against vivisection by cultured thought
cultured speech. We will therefore confine our
narks to what was said on this side of the question.

Regarded as a piece of oratory, the speech of Canon
don was, in our opinion, perfect; and the effect of
it we may term an artistic eloquence was enhanced by
appearance and costume of the speaker, as well as by
appropriateness of his surroundings in the densely
vded Sheldonian Theatre. But when we look from
manner to the matter of his speech, we are unable to
ow such unqualified praise, although we confess that
here we were agreeably surprised by the judicious
leration of its tone. His views, briefly stated, were
so long as we hold it morally lawful to kill animals
food, or otherwise to use them for our own purposes,
ong must we in consistency hold that, under certain
umstances, it is morally lawful to inflict pain upon
nals for the benefit of man: the special case of vivi-
ion does not differ in principle from other cases where
is thus inflicted; but it ought to be qualified by
e conditions—it should be resorted to as rarely as
ible, it should be guarded against the instinct of
lty, and it should be so used as not to demoralise
tators. With all this every physiologist would of
se agree. The Canon, however, proceeded to talk
in the strictest meaning of the word must be termed
ense, when he affirmed that physiology might be
orced" from vivisection. That this statement has
ed currency among the anti-vivisectionists does not
its essentially unreasonable character. It is per-
true that in many departments of physiological
rch vivisection is not required; but it is no less true
in many other departments vivisection is an uncon-
ial necessity. This fact, one would think, admits of
rendered obvious to any impartial mind, howsoever
rant of physiological science. For if this science
sts in the study of vital processes going on in the
f organism, does it not obviously follow that some of
can only be studied while actually taking place?
for example, would it be possible to gain any know-
of the electrical and other changes which occur in
mating these changes during the act of secretion? The gratuitous information which physiologists receive from technically ignorant sources touching the nature and the value of their own methods, can only suggest the presumption of inexperienced youth when venturing to instruct a maternal grand-parent in the practical aspects of oology.

It appears that Prof. Burdon-Sanderson had pledged himself not to exhibit vivisections to his class for the purposes of teaching, and for this concession to the unreasoning prejudice of his opponents he received a warm expression of gratitude from Canon Liddon. Probably enough, under the circumstances in which he is placed, the concession is a prudent one; but that it merited the eulogium which was bestowed upon it by Canon Liddon on moral grounds, no man of common sense could very well suppose. Demonstrations on the living subject, if performed in a class-room at Oxford, would of course be always performed on animals under the influence of anæsthetics; and therefore the "demoralising" effects upon the minds of young men, which Canon Liddon takes to have been averted by Prof. Sanderson's concession, can only be understood to consist in disregarding the mawkish sentimentality which cannot stand the sight of a painless dissection. This kind of "morality" may be regarded as tolerable in a girl; in a man it is not tolerable, and deserves the same kind of pitying contempt as is accorded to personal cowardice, with which it is most nearly allied.

Canon Liddon, however, regretted that Prof. Sanderson had not further pledged himself to restrict his experiments *for the purposes of research* to animals kept under the influence of anæsthetics during the operations, and killed before recovering from their anæsthesia. We have no doubt that Prof. Sanderson might have complied with the first of these suggestions without any serious detriment to his future researches. For, as a matter of fact, the cases in which anæsthetics interfere with the progress of an experiment are, comparatively speaking, very rare indeed, except where the occurrence of pain forms a necessary part of the experiment—*i.e.* in certain researches on the functions of sensory nerves. But as all the functions of sensory nerves which require for their study the infliction of pain have already been worked out, physiology as it now stands does not demand the absence of anæsthetics, save in a very small per centage of operations. Therefore, when pain is inflicted during an operation, it is due, as a rule, not to the exigencies of research, but to the indifference of the operator—a fact which we think physiologists ought to be more insistant than they are in impressing upon the mind of the public. Nevertheless, we feel persuaded that Prof. Sanderson was perfectly right in not binding himself never to operate without anæsthetics; for by so doing he would have virtually conceded the principle that the suffering of an animal is too great a price at which to buy an advance of knowledge; and this, among other things, would have been to place a moral stigma upon some of the most valuable researches of the past. Besides, as was pointed out in the course of an able speech by Prof. Dicey, it is not desirable that the *status* of a Professor in the University should be regarded as beneath that of a gentleman; and if it is supposed that Dr. Sanderson is not to

be trusted in the latter capacity, he ought never to have been chosen to fill an Oxford chair. In short, as the representative of physiology in Oxford, Dr. Sanderson, by the nature and extent of his concession, has drawn a clear distinction between the importance of teaching and of research: he has consented to allow the teaching to suffer if needs be; but he will not consent to yield an inch where the principles of research are concerned.

The other suggestion which was thrown out by Canon Liddon—namely, that a Professor of Physiology ought to pledge himself to kill every animal before it recovers from its anæsthesia—is, from every point of view, absurd. In the first place, the suggestion can only emanate from the uninformed supposition that the pain of a healing wound is considerable. But we know from the experience of hospital practice that even the most severe wounds are painless while healing, unless the process of healing is complicated by morbid conditions, which now admit of being wholly prevented by antiseptic methods. As a matter of fact, therefore, in our physiological laboratories, as in our surgical wards, there is at the present time but an extremely small amount of suffering to be found in connection with the healing of wounds; and no man of ordinary sense who had ever seen the inside of either the one or the other would have cared to make the suggestion which we are considering. But, in the next place, even if this were not so, it would have been highly wrong in any Professor of Physiology to restrict himself to the performance of experiments the objects of which could be secured during the action of an anæsthetic. Certainly more than half the experiments which the physiologist has now to perform have reference to questions of after-effects, and this is especially the case in experiments bearing upon the problems of pathology.

The speech of the Bishop of Oxford was bad, both in logic and in taste. It was bad in logic because in arguing for the total suppression of physiological research in Oxford, he relied upon foreign practice for his evidence of cruelty. This was essentially illogical, because it fails to distinguish between two very different things—namely, the cruelty, if any, which attaches to vivisection *per se*, and the cruelty which arises from other sources. If the state of public feeling in some foreign countries is not so sensitive as it is in our own on the matter of inflicting pain upon the lower animals, it is obviously unfair to search through the Continent for instances of cruelty in connection with physiological research, and then to adduce such instances as proof of cruelty necessarily attaching to physiological research at home. We might as well argue against the use of mules in England because these animals are badly treated in Spain. As we have already said, there are now but extremely few cases possible in which the occurrence of pain is necessary for the purposes of an experiment; and therefore the proof of pain having been inflicted in any one case constitutes proof, not of the pain-giving character of vivisection in general, but of the carelessness of some operator in particular. The cruelty must belong to the individual, not to the methods; and we are not aware that any charge of cruelty has hitherto been proved against an English physiologist.

The Bishop of Oxford's speech was bad in taste, because he sought, missionary-wise, to tell some anecdote of horror, which the good sense of Convocation prevented him from narrating further than that the subject of the story was to have been "an affectionate little dog." But, as he was not able to give any reference to the scene of his tragedy, after a prolonged battle with his audience upon this somewhat necessary proof of authenticity, he was obliged to give way. His taste was perhaps still more questionable when, in the presence of Prof. Sanderson and other working physiologists, he proceeded to adduce the favourite argument that the pursuit of experimental physiology exercises a baleful influence on the moral nature. That the argument is unsound, both in principle and in fact, we need not wait to show.

The speech of Prof. Freeman was rendered wholly inaudible by a general uproar, which proceeded chiefly from the side which he rose to support. We were told that this was due to the memory of the effect which was produced by his speech on the occasion of the previous vote.

Upon the whole we think that the debate was of a little service to the cause of physiology in Oxford; and when we consider how largely the majority of votes has grown since the first of the three divisions, we are glad to congratulate the University upon having shown so emphatically that, not less than her sister, she is able to withstand the assaults of the two great enemies of learning—Ignorance and Fanaticism.

THE RELATIVE EFFICIENCY OF WARSHIPS

IN our last week's issue we published a letter from Sir Edward Reed adverting to some points in an article which appeared in our number of February 26 upon "The Relative Efficiency of War Ships." In order to show the difference existing between the ships of the *Inflexible* or *Agamemnon* class and those of the *Admiral* class, as regards height of armour above the water, we then gave profiles of the *Agamemnon* and of the *Collingwood* (one of the *Admiral* class). We now give outline sections of the same vessels, in which this large difference can be more clearly seen, and by means of which its importance can be better understood.

Before giving any figures in connection with this question it may be as well to mention another point which, taken alone, is not unworthy of notice. We refer to the difference between the *Agamemnon* and *Collingwood* with regard to depth of armour below the water. When the *Agamemnon* is floating in smooth water, with her armoured ends uninjured, the depth of her armour below the water-line is 5 feet 10 inches, whereas that of the *Collingwood*, under the same conditions, is only 5 feet, as shown in Figs. 1 and 2 respectively. This difference of nearly 1 foot is of some importance, because every one of the three inches gained in depth of armour below the water means a large increase in the safety of the ship when fighting at sea. When the ends of the *Agamemnon* are flooded she sinks 22 inches deeper in the water, and the depth of her armour below its surface would, therefore, then be 7 feet 8 inches (Fig. 3). The *Collingwood*, when her ends are flooded, sinks 17½ inches deeper in the water, and in that condition, therefore, her armour would be 6 feet 5½ inches below the water's surface (Fig. 4), or 1 foot 2½ inches less than that of the *Agamemnon*. In the earlier ironclads it was considered necessary to

he armour to a depth of at least 6 feet below the normal water-line, and as much deeper as individual cases would allow. It is evident, therefore, that the ships of the *Admiral* class are deficient in this respect unless and until their unarmoured ends are flooded.

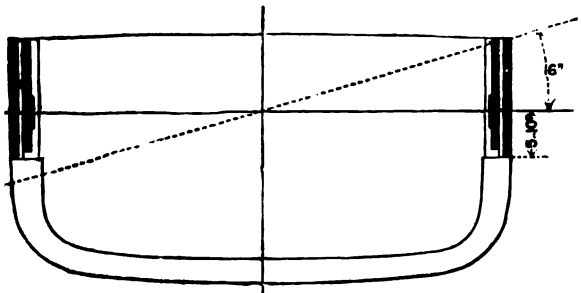

FIG. 1.—*Agamemnon.*

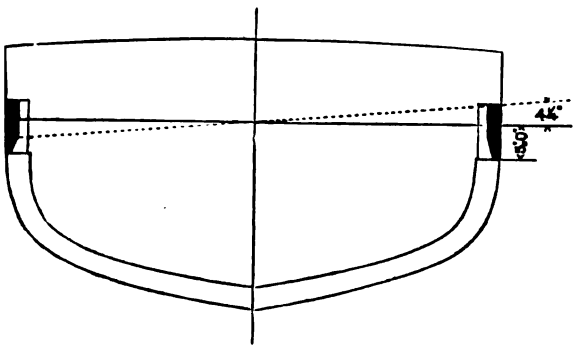

FIG. 2.—*Collingwood.*

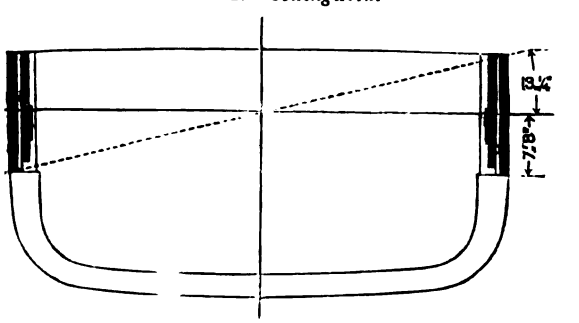

FIG. 3.—*Agamemnon.*

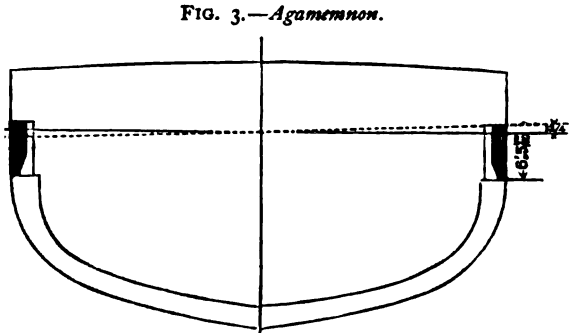

FIG. 4.—*Collingwood.*

Reverting to the still more important question of height of armoured freeboard (*i.e.* the height of the top edge of armour at side above the water), we will now give some figures. The *Agamemnon*, with her armoured freeboard of 9 feet 6 inches in the uninjured condition, can be inclined to the angle of 16 degrees before the top edge of her armour touches the water, as shown by the dotted line in Fig. 1; and even when her unarmoured ends are flooded, and her freeboard therefore reduced to 7 feet 8 inches, she can still be inclined (assuming for the moment that she would still have stability) to the angle of 13½ degrees before her armour is brought beneath the water; this is shown in Fig. 3. But the *Collingwood* has so ridiculously shallow a partial belt (only 2 feet 6 inches above the water in the uninjured condition) that an inclination of only 4½ degrees causes her armour to disappear altogether in smooth water. When her ends are flooded her armoured freeboard is actually reduced to no more than 12½ inches, which is as much as to say that at sea she would have no armoured freeboard at all in that condition, for an inclination of but 1⅞ degrees is sufficient to bury her armour completely, even in smooth water. The two conditions of the *Collingwood* are shown in Fig. 2 and Fig. 4 respectively.

These alarming facts, thus clearly brought into view are of themselves sufficient to explain Sir Edward Reed's distrust of the *Admiral* class of ship, and his very strong condemnation of these ships can be readily understood when we remember, further, that in his opinion the excessive shortening of the armoured part in the whole of these ships has introduced such elements of danger into them as to render them unfit to take their place in the line of battle, even apart from the considerations previously set forth.

THE AMERICAN ASSOCIATION

Proceedings of the American Association for the Advancement of Science (Thirty-Second Meeting), held at Minneapolis, Minn., August, 1883. (Salem: Published by the Permanent Secretary, 1884.)

THE record of the proceedings of the thirty-second meeting of the American Association forms a volume considerably less bulky than that issued by the British Association, as it consists of 598 pages, the corresponding volume of the older Association numbering 884 pages. The difference between the two volumes, as records of science, is about in the same proportion. Addresses, reports, and abstracts of papers take up 468 pages in the book before us, while in the Southport volume the same subjects occupy 660 pages. In printing and paper the American volume is decidedly the superior of the British, but, as a set-off, it is issued in a paper cover; the price, however, is only 1·50 dollars. The smaller size of the volume is accounted for by the fact that considerably fewer papers appear to have been read before the American Association than before the British. We note also another point of difference, certainly not to the advantage of the American volume: the reports on the state of science, so conspicuous and valuable a feature in the British volume, are remarkable in the American chiefly by their absence. We venture to suggest to the officers and Committee of the latter Association that they would add largely to its importance and stability by developing this branch of its work. At the present time, when scientific societies for special purposes are so numerous, their meetings and journals will always compete successfully with those of an all-embracing Association such as the British and others formed on a similar plan

for original papers of real importance; but the task of recording progress, of acting as the historians of science, is rightly declined by societies which aim at advance rather than at retrospect. Hence this most important function can be best discharged by these great Associations, and it will always suffice to save them from degenerating into scientific camp-meetings or picnics.

The Sections in the American Association are equally numerous with those in the British at the present time, though differently arranged. Mathematics and Physics are divided, Geology and Geography united; Histology and Microscopy form a section separate from Biology. We doubt the advantages of the union in the second case, and of the separation in the third. That no address is printed in this volume, and that the only record of the proceedings of the Section of Histology and Microscopy is the statement that, although some meetings took place, no papers were read before it, seems an indication that, as in Britain, its subjects might safely be merged in Biology, the latter Section having the power of temporary subdivision.

In another respect too the American differs from the British Association. In the latter the delivery of an address is the first official act of its President, in the former it is the last. The address at Minneapolis was delivered by Principal (now Sir William) Dawson, and is characterised by the scientific caution and literary ability of its author. It gives a critical sketch of the results of geology, more especially with reference to the development of the earlier rocks and to the evolution of living creatures. In regard to the former, Sir W. Dawson inclines to drawing a marked line of separation between the Lower Laurentian or Ottawa gneiss of Sir W. Logan and the Middle Laurentian or the Grenville series of the same, which is characterised by beds of limestone and dolomite, "quartzite, quartzose gneisses, and even pebble beds," besides graphite, iron ore, and the debatable *eozoon*, which Sir W. Dawson considers as indicating the existence of land surfaces of the fundamental gneiss. The Upper Laurentian or Norian series is noticed with due caution, though it is regarded as decidedly younger than the preceding formation. The Huronian, Montalban, and Taconian (Lower Taconic of Emmons) are next mentioned, but the author, though inclining to the views of Dr. Sterry Hunt as to their order of succession, forbears to dogmatise as to their precise relations either mutually or with "certain doubtful deposits around Lake Superior." With regard to the development of life, he is decidedly adverse to the evolution school among biologists, but is not able to add anything material to the familiar arguments of its opponents. The address concludes with a brief notice of some of the obscure markings, variously referred by palæontologists to algæ, protozoa, and tracks of various animals, and with a critical sketch of the theories relating to the Glacial Epoch, in which he expresses himself as opposed to the extreme views of the former extension of land-ice and its erosive action which are favoured by some geologists.

Two other papers are given as "read in General Sessions," which we presume may be regarded as in some respect analogous with the evening discourses at the British meetings. The one by Dr. Sterry Hunt, "On a Classification of the Natural Sciences," is printed in abstract only; the other, by Prof. E. D. Cope, entitled "Evidence for Evolution in the History of the [illegible] Mammalia," is an extremely able and temperate [illegible] of the views antagonistic to those entertained [illegible] retiring President. "The German Survey of the [illegible] Heavens" forms the subject of an interesting addr[illegible] Prof. W. A. Rogers, who presided over the sec[illegible] Mathematics and Astronomy, and Prof. H. A. Rowla[illegible] vered a "Plea for Pure Science" to the section of [illegible] Both these sections received a considerable num[illegible] communications. The section of Chemistry [illegible] appear to have had a special address, and the num[illegible] papers read before it was not large. The same [illegible] said of the Mechanical Section, in which only [illegible] papers are recorded as read. Prof. Hitchcock [illegible] section of Geology and Geography, took the "History of the North American Continent" as the [illegible] of his address, in which he favours the idea that [illegible] of the early crystalline rocks are of igneous origin [illegible] metamorphosed volcanic rocks or tuffs. Ice [illegible] leavings form the subject of a large proportion [illegible] papers read before this section. More than one [illegible] is of much interest, especially that by Mr. W. [illegible] on the Minnesota Valley in the Ice Age. [illegible] H. C. Bolton and A. A. Julien describe "The [illegible] Beach of Manchester, Mass.," noticing in the [illegible] of the paper the sonorous sand in the [illegible] Eigg (Hebrides), as well as others on record [illegible] sults from their observations that the sound [illegible] the grains, which are not rounded, but have [illegible] angular surfaces. It is, we think, undoubtedly a [illegible] phenomenon. We are acquainted (probably the [illegible] common) with a small screw-tap in a lavatory [illegible] loudly sonorous when a certain amount of [illegible] allowed to issue, but silent in other positions. [illegible] Beal, in addressing the Section of Biology, deals [illegible] culture, its Needs and Opportunities;" and the [illegible] received a considerable number of interesting com[illegible] tions. Dr. Franklin B. Hough addressed the [illegible] Section on the method of statistics, and the [illegible] Mr. E. B. Elliott, delivered to the same Sect[illegible] preceding Montreal meeting, is printed in the [illegible] This Section does not appear to receive nearly [illegible] communications as the corresponding one of [illegible] Association. The address of Prof. O. T. Mas[illegible] Section of Anthropology deals with the scope [illegible] of anthropological studies, and a considerable [illegible] interesting papers were read. Those relating [illegible] building may be of service to European archæ[illegible] offering suggestions which may help in the int[illegible] of some of the earthworks in the Old World.

On the Terminology of the Mathematical Theory of Elasticity

THE late Dr. Todhunter left, in an incomplete [illegible] able "History of the Mathematical Theories of [illegible]

which the syndics of the Cambridge University Press have intrusted to me to complete and edit. In reading the great number of memoirs relating to the subject I have been much struck by the want of a clear and accurate terminology in both theoretical and practical elasticity. I have been forced to the conclusion that the great discrepancy, which is often to be found between theoretical and practical results, is in some measure due to the want of this terminology (*e.g.* the extreme looseness of the term "limit of elasticity"). I find it needful for the purposes of the above work to adopt such a terminology, but before doing so it would be extremely valuable to have the opinion of some of our leading elasticians on the terms I venture to propose. I should be very glad of any suggestions, through the columns of NATURE, towards a definite and uniform terminology.

I am particularly dissatisfied with the term "limit of superimposition." It is exceedingly clumsy. Other possible terms are—"limit of superposable stress," "linear limit," and "limit of constant slope," the last two phrases having reference to the fact that the stress-strain curve at this limit ceases to be a straight line. With regard to this limit of superimposition I may remark that it may arise from one of two causes—(1) The strain components become so large that we cannot neglect the squares of small quantities, or the stress components can no longer be taken proportional to those of strain. This might happen before permanent set. (2) Permanent set may arise which does not follow the generalised Hooke's Law. This seems the more probable case, and has been adopted below. Prof. Kennedy tells me that he thinks when a body has been reduced to a state of ease that the superior elastic limit and the limit of superposition coincide.

It has been proposed, I believe, to term that limit of stress at which bars begin locally to "thin down" the limit of viscosity. The "limit of uniform strain" is not altogether satisfactory or quite suggestive of this peculiar viscosity. "State of maximum stress" might perhaps serve the purpose, were one quite sure that this state always coincides with the viscous limit.

In the following remarks I have been much assisted by Prof. Thomson's epoch-making paper in the *Cambridge and Dublin Mathematical Journal* for 1848, and even more by Prof. Alex. W. Kennedy's paper on Riveted Joints in the *Proceedings* of the Institution of Mechanical Engineers, April, 1881 (especially pp. 208-213).

We have first to distinguish between two classes of materials. In the one we may suppose the particles to be in a state of internal stress before any external force is applied; in this case a, the least, external stress will probably produce permanent set. If this stress be removed and then reapplied, after one or two trials it will cease to produce permanent set, or at least the permanent set will be extremely small as compared with the elastic strain. We thus need a term to mark that state of the body when external stress does not produce permanent set owing to the existence of internal stress. This might perhaps be termed *state of ease*. Many discordant results with regard to the constants of elasticity are not improbably due to the fact that the ratio of stress to strain has been measured before the material has been reduced to a *state of ease*. In the second class of materials we may suppose this state of ease to exist before the application of any stress. Supposing a body to be in its state of ease, there will then exist two limits, one on one side, and one on the other of the unstrained shape, which may be termed *inferior and the superior limits of perfect elasticity*. Any external stress which does not produce a strain exceeding these limits will not give rise to permanent set. These inferior and superior limits of perfect elasticity mark, as a rule, the range covered by the usual mathematical theory. Within these limits it is generally safe to assume that the components of internal stress are proportional to the components of strain. In some cases, *i.e.* cast iron, where, however, it is difficult to produce a state of ease, this does not seem to be accurate—the stress and strain components appear never to be proportional.

In most materials the range of perfect elasticity is not large. Any external stress, which is by no means nearly equal to that which is required to produce rupture will give rise to a permanent set. Thus permanent set in some materials will commence at a stress only ⅓ to ½ of the stress that those materials are capable of standing. Thus beyond the limit of elasticity we have first a range of stresses, which produce strains partly elastic and partly permanent. The strain in this range might still remain proportional to the stress; the permanent is yet small as compared with the elastic part of the strain. This range is bounded, however, by a stress for which the strain ceases to be proportional to the stress. In other words, the "generalised" Hooke's law is no longer applicable. Up to this point, if we are merely desirous of finding the strain produced by any system of statical stress, the mathematical equations of elasticity will apply, supposing, as seems probable, that the elastic constants do not alter, owing to the permanent set. Those equations would not of course be valid if we wished to find the strain in the body, if the stress were altered, nor would they suffice to treat vibratory motions capable of producing permanent set. This limit, which is that at which the *ut tensio sic vis* principle ceases, requires a name. It might perhaps be termed the *limit of superimposition*. That is to say, if a certain addition to this limiting stress produced a certain increase of strain, and a second addition another increase, these increments of stress, if superimposed would not produce the sum of the strain increments. It might at first sight appear more direct to term it the modular limit, or the limit of Hooke's law, but it would seem that, after this limit is passed, Hooke's law, probably with the same modulus, applies to so much of the strain as is elastic strain; in fact at the limit of superimposition it is the permanent set part of the strain which ceases to obey Hooke's law. In some materials the limits of perfect elasticity and of superimposition may coincide. At the latter limit the permanent set is still in some cases only one-twenty-fifth of the total strain. Neither of the limits above considered is *commercially* treated as the limit of elasticity. This is the point at which the material "breaks down," that is to say, the stress being continually increased, a strain is obtained which would be preserved by replacing the stress by one very much less. The material is unable to balance the stress upon it. If the stress be maintained the strain will suddenly increase by a considerable amount (without the stress being increased). This remarkable limit, it has been suggested by Mr. Tweddell, should be termed the *limit of fatigue*. The limit of fatigue being past, a small proportion of the strain, namely, so much as corresponds to the modulus, is elastic, the greater part is permanent set.

In the case of bars of iron subjected to longitudinal pull, if the stress be increased beyond the limit of fatigue, another limiting strain is reached, namely, one at which local contraction begins, or the bar commences to draw out at some point, *i.e.* the strain ceases to be uniform. The material now begins to act as if it were "viscous," and it would be convenient to describe this state as that of *viscosity*, had not this name been appropriated to that permanent set which may be produced by the application for a long period of a stress well within the limits of perfect elasticity. Closely associated, if not the same, with this *limit of uniform strain* is the state of maximum load. From this point onwards, as the strain increases the load decreases, till the breaking load is reached with a magnitude below that of the maximum load. To distinguish one from the other requires a special manipulation. As a rule, what is meant by the *absolute or breaking strength* is probably the *maximum load*, for if this load was allowed to remain, the bar would break under it. It might perhaps be convenient, however, to speak of one as the *maximum* and the other as the *terminal load*. With the terminal load the "elastic life" of the material is concluded. It must be remembered that owing to the bar locally thinning down, the stress per unit area at the terminal load is greater than the stress per unit area at the maximum load.

Such are the limits for which it is needful that a terminology should be established. I shall be extremely glad if any of the readers of NATURE, who happen to be elasticians, will suggest a more concise phraseology.

Civilisation and Eyesight

I HAVE been interested in Lord Rayleigh's note on "Vision," and would offer my mite on the subject.

I have no doubt that brilliancy of image and power of distinguishing largely depend on definition. The brilliancy does so for the same reason as that which induces an artist to heighten colour-effects by sharp contrasts. In the same way, if we seek to decide if two colours are alike, we place them in immediate contact with a sharp edge. Details are best seen with a telescope when the images are sharp and untroubled. When slight tremors are in the air, and the image is rapidly displaced in all directions, so that what we see is the resultant

of many rapidly succeeding impressions, then tints are graded into one another at the edges, and we lose the power of distinguishing detail.

I can give, fortunately, a case in point. My eyes are affected with a small amount of astigmatism. It does not affect general vision for ordinary purposes, nor, of course, the definition of single lines; but, when I use appropriate lenses, the whole scene becomes brighter and more cheerful, and I see details. The bark of a tree is a perfectly different object with and without them. With them it is like a go of photograph; without them, like many pictures. Formerly, in addition to the cylindrical surface, I required a slight spherical concave, and I was disposed to place the increased general brilliancy of the view mainly to the reduction of size, but I now use plano-cylindrical lenses for distant vision, and it is evident that the brilliancy is solely due to the better definition.

I would, lastly, suggest for Lord Rayleigh's consideration the question whether the change of focus of his eyes in faint light is not partly, at all events, due to change in the colour of the light. I know that there is such a change with me, but I have long had reason to believe that colour affects my vision.

J. F. TENNANT

37, Hamilton Road, Ealing, W., February 7

THOSE who have compared Lord Rayleigh's letter in NATURE of February 12 with that of Mr. Brudenell Carter on February 26 will have observed an inconsistency occasioned by a slip of the pen.

The latter says: "The commonly accepted standard of normal vision is satisfied by deciphering letters the parts of which subtend visual angles of one minute. . . ." Also, Prof. McKendrick states that "The smallest visual angle in which two distinct points may be observed is 60 seconds."

According to Lord Rayleigh, however, "A double star cannot be fairly resolved unless its components subtend an angle exceeding that subtended by the wave-length of light at a distance equal to the aperture. If we take the aperture of the eye as 1/5th inch, and the wave-length of light as 1/40,000th inch, this angle is found to be about two minutes." In the case of a small angle the aperture divided by the distance is approximately equal to the arc divided by the radius or to the circular measure of the angle. Hence in the present case we have $\frac{1/40{,}000\text{th inch}}{1/5\text{th inch}} = \frac{1}{8000}$ radian or $\frac{206{,}265}{8000} = 25{\cdot}8$ seconds nearly, instead of the two minutes accidentally stated by Lord Rayleigh.

This minimum value seems to show some mistake in Ehrenberg's experiments on vision, and is about half of that found by Helmholtz for the best of twelve observers.

March 10 SYDNEY LUPTON

[Mr. Lupton is quite right. By a stupid blunder I said about two minutes, when I should have said about half a minute.—RAYLEIGH.]

THERE is a defect of eyesight common among the natives of India known as "rátaudhí," *lit.* "night blindness." Persons affected with this have either ordinary powers of vision by daylight, or else powers so little less than ordinary as to feel no inconvenience, so that usually no defect is noticeable; whilst in feeble twilight their sight fails in the most extraordinary way, and in the dusk they become (in bad cases) practically blind. Of course there are all degrees of this affection; but the strongly-marked cases alone are likely to attract attention.

By medical men in India this affection is said to occur most among men living on a low diet (chiefly of cereals), and the usual palliative treatment is to prescribe a meat diet.

This affection is rarely noticeable among Europeans in India, though I have sometimes noticed marked differences of clearness of sight among them also amounting to slight "night-blindness." Lord Rayleigh's case of short-sightedness in twilight and in the dusk seems to be a mild case of this sort (see NATURE, February 12, p. 340).

ALLAN CUNNINGHAM

The Pupil of the Eyes during Emotion

ALTHOUGH further observations are required, there seems to be a more or less general assent as to the influence of the emotions on the pupils of the eyes. Mr. Clark, in his letter to your journal (vol. xxxi. p. 433), has rightly quoted Gratiolet, who says that in sudden astonishment or fear the whole system becomes paralysed, and at the same time the pupils dilated. In anger, on the other hand, when the whole body is roused into action, the pupils become contracted: "Les pupilles sont énormément dilatées dans l'épouvanté, tandis qu'elles sont toujours contractées dans le colère." This was, however, said many years before by the celebrated Harvey, who, in his discourse on the circulation of the blood, written in 1628, says: "In anger the eyes are fiery, and the pupils contracted" ("In ralisent iculi, constringitur pupilla").

I should myself think that a narrow pupil evinces a more active mental state, as it is this condition which is present when the eye is accommodated to regard with attention a near object, whilst, on the other hand, when gazing out into distance, the pupils are wider, and the mental mood is more passive and contemplative.

In my parrot the size of the pupil is a very excellent measure of its frame of mind. When angry the pupil becomes minutely contracted, whereas when the bird is sympathetic and amiable the pupils become as widely dilated. Balzac, with other novelists, have depicted the state of the pupils when describing the various emotions and passions. The former in portraying a saintly woman kneeling before the altar, says: "The pupil of the eye, endued with great contractility, appeared then to expand and draw back the blue of the iris until it formed a more than a narrow circle. What force was that arising in the depths of the soul which so enlarged the pupils in full daylight and obscured the azure of those celestial eyes?" Darwin speaks doubtfully, but rightly demands more observations on the subject.

SAMUEL WILKS

Grosvenor Street, March

Auroræ

AFTER a long and remarkable absence of aurora, which, as a letter in your columns of February 19 (p. 360) does not appear to have been confined to these more southerly latitudes, we were favoured last evening with a beautiful, though somewhat transient display. It was about 9'25 p.m. when I first noticed a long band or belt of light above the northern horizon. At first it was ill-defined, with little change of position, but in about twenty minutes it became more luminous and the characteristic streamers suddenly made their appearance, shooting upwards sometimes from above, sometimes from below the belt of light, which for a few seconds changed into a double arch. Soon these streamers rose as distinct columns, showing the usual prismatic hues, one in particular being noticeable as traversing the inverted W of Cassiopeia, another forming a fine terminus to the luminous region, but all confined to a low latitude, bounded on the north-west by Perseus, and on the south-east by Vega, then rising. It may be well to observe that on the same day (the 15th) a large sun-spot had just reached the central meridian, and was beginning to show signs of disturbance.

Injuries caused by Lightning in Venezuela

IN answer to Mr. von Danckelman's inquiry as to the lightning-rods and the frequency of accidents from lightning in the tropics (NATURE, December 11, 1884, p. 127), I beg to offer the following information referring to Venezuela, where I have been residing ever since 1862:—

Thunderstorms are very frequent during the rainy season. They break out generally in the afternoon, about the time of the daily maximum of heat, whilst they are extremely rare in the morning (I only witnessed one case) and during the night. Statistics of accidents do not exist, nor are there many lightning-rods in use (in Caracas about half a dozen). But there are certain regions where the former are far from being rare, as, for instance, the country around the Lake of Valencia, the plains or *llanos* to the north of the Orinoco. In these regions a considerable number of cattle are killed by lightning every year, and also of several cases where houses were destroyed and persons killed. The herds of cattle crowd together as soon as a thunderstorm begins, and the animals remain during the whole time with their heads down to the ground, thus avoiding instinctively that their pointed horns should act as lightning-conductors.

In the neighbourhood of Maracay, at the eastern end of the Lake of Valencia, accidents occur almost every year.

remarkable one was witnessed in 1583 by Dr. Manuel A. Diez, that time physician of the military camp at Maracay. A ghtning struck a *rancho* (small country house built of wood and ud, and thatched with straw or large leaves), where a man ept in a hammock, another lay under the hammock on the round, and three women were busy about the floor; there were so several hens and a pig. The man in the hammock did not ceive any injury whatever, whilst the other four persons and e animals were killed. As the wooden framework of the ouse was probably very dry, the man in the hammock was most isolated; but the other persons and the animals were direct contact with the floor—in this case the bare ound.

Near Caracas accidents are comparatively rare. During all e years of my residence here no more than six have come to y knowledge: in three of them some damage was done to ildings, in two cases large trees were split, and in one October, 1882) a ploughman was killed while at work in the ld, together with his two oxen, his driving-stick (about four rds long, and shod with an iron point) having acted as ghtning-conductor.

A. ERNST

Caracas, February 8

Mira Ceti

WITH reference to your note on Mira Ceti in NATURE of bruary 5, I beg to say that I have observed Mira since cember 15, 1884, and my observations show that the star ched a maximum on February 4, when I estimated it equal a Ceti, or about 2·7 magnitude. It remained of the same ghtness up to February 13, and has faded very slowly since t date. It was, last night, not much below a Ceti.

J. E. GORE

Ballysodare, Co. Sligo, Ireland, March 8

Physical Geography of the Malayan Peninsula

HOPE you will give me space in your journal to correct a errors that have slipped into the letter under this heading he issue of December 18 (p. 152) by the Rev. J. E. Tenison-oods.

n the first place, there is no flint-spar in the drift which ies the tin. The stone referred to is rose-quartz, some of ch is very beautifully coloured. I have a specimen of it rly as large as a man's head. It has a specific gravity of , and hardness equal to ordinary white quartz, which it will tch without difficulty.

n the next paragraph Mr. Tenison-Woods says he cannot all any mines on the eastern slopes of the mountains. This ns extraordinary, as some of the best mines in Kinta are on eastern slopes of the valley, and I accompanied Mr. Tenison-oods to the Lehat, Pasir, and Papan mining districts, and, the exception of the Kwala, Dipang, and Gopeng mines, e were the only ones visited by him in Kinta, which were on the eastern slopes of the Kinta valley. "The river flows, he says, speaking of the Kinta valley. "The river flows, the Perak, on the eastern side of the valley." This is also stake, for it is decidedly on the western side, and this ac-ts for the fact mentioned in the next line: "The eastern taries are many and important." If the rivers were as d by the rev. gentleman, this would be nearly impossible. e taken the opportunity of asking the opinion of the officer harge of the Kinta district, and he coincides with my view e position of the river.

he next point on which I cannot agree is that "there is not ightest sign of any recent upheaval of the coast line, while vidence of subsidence is equally absent. A short time ago ing was made to a depth of 75 feet at Marang (which is ort of Larut), and I made a section from it, which s that, within quite recent times, an important alter-of level has taken place. The ground at that place is above the present high-water mark. Down to a depth of t from the surface the formation is marine, but below that of sands, clays, and gravels, with leaf-beds and pieces of are met with, of the same nature as the drift near the and containing a small quantity of fine tin; these beds down to a depth of 75 feet, and most probably much r. It therefore appears that there has been a subsidence feet since the formation of the tin-bearing drift of Larut. An alteration of level of this extent must have made most important geographical changes in the Straits of Malacca, and may help to solve many of the problems connected with the distribution of the flora and fauna of this interesting locality.

The limestone-hill on the eastern side of the Gapis Pass, called Gunong Pondok, is 1800 feet in height, instead of 4200 feet, as stated; and is connected by a ridge with the main range of mountains. A little further on Mr. Tenison Woods says that there are *two* mountains called Gunong Hijau. This is a very excusable mistake for a stranger to make, for one is Hijau, which means "green," and the one further to the north is Ijoh, which is the name of a palm (*Arenga saccharifera*). The Kerau river has its source on the former mountain, at the back of the town of Thaipeng. About four years ago I followed the stream from near the summit of Hijau down to the plains.

Perak Museum, Larut, Perak, January 30

The Continuity of Protoplasm in Plant Tissue

THERE is some danger that those who are unable to make a personal examination of the Floridæ may be a little misled by Mr. Gardiner's remarks thereon in his article on "The Continuity of the Protoplasm in Plant Tissue" (NATURE, vol. xxvi. p. 390). In arguing in support of his own view that this continuity is not direct, but indirect, he states that "Schmitz has found that a pit-closing membrane," "perforated in a sieve-like manner," exists in the Floridæ, and that he himself has "been able to confirm Schmitz's results as to the existence of the closing membrane in question."

Now, if Mr. Gardiner means by this that what he terms a pit-closing membrane, perforated in a sieve-like manner, is present in *all* the Floridæ, or even in *all parts* of the thallus of a single species, I venture to submit that the statement is not in strict accordance with fact. In my investigations into the histology of these plants, special attention was paid to this point, and by no methods that I could devise, or learn from other workers, was such a membrane to be demonstrated in the simpler forms, as, for example, in *Petrocelis cruenta*. Indeed, I cannot conceive how a sieve-plate arrangement could possibly exist, where the continuity is maintained by *a single thread of protoplasm*, and that of such extreme tenuity as in the species referred to. So far as I am aware, no one maintains the existence of a sieve-plate in the threads of Volvox, and I fail to see why it should be assumed to exist in the equally fine threads now under consideration.

Further, in *Polysiphonia*, *Pilota*, and other genera, where a membrane is normally present, it is *not* met with *in every part* of the thallus, being absent from the younger portions. In these portions the connecting threads are *single* and *extremely delicate*, so that while observation affords no indication of a sieve-plate, the arrangements themselves preclude the possibility of one. As the threads grow older and thicker, a membrane which may be perforated is developed, but it is no part of the primary wall of the protoplasm. Thus, while the connecting protoplasmic threads exist from the first, the so-called pit-closing membrane arises as *a later development*, and is therefore *subsidiary to the continuity*, and *not essential* to it.

So far, then, as the Floridæ are concerned, I think we must recognise two conditions or stages of continuity: first, a direct continuity, permanent in the simpler forms, but transitory in the more complex ones; and second, an indirect continuity, absent from the younger, but present in the older tissues.

THOMAS HICK

Harrogate, March 7

Time in the United States

IN your issue of January 23 the statement (p. 277) that "local time throughout the United States, as opposed to railway time, has been abolished," is not quite accurate. At the introduction of the "standard" time an attempt was made in many places to do this, but it has proved impracticable, except near the meridians of time. At other places the local time still governs all the daily business, except what involves travelling. For this the difference, a constant quantity, is remembered, and the proper allowance made. For example, here we allow thirty-three minutes, being west of the meridian of eastern time to that amount.

E. W. CLAYPOLE

FACILITIES FOR BOTANICAL RESEARCH

THE botanical student who has successfully passed his final examination at one of our universities or local colleges will naturally begin to consider to what use he can devote the knowledge of facts and methods which he has acquired. To many it is unfortunately necessary to turn at once to some employment which will bring in a substantial return. Teaching pays; research does not; so the latter is often out of the question. But the few to whom earning money is not an immediate necessity hardly realise the splendid possibilities which lie before them. Of these men of more or less independent means some, from pure inertness, may be content to move within the narrow circle of their own university; others, following the example of their predecessors, will start on the German pilgrimage and sit at the feet of one or other of those teachers whose names they have long venerated from a distance. The advantage of working under the direction of one of these masters is no doubt very great, but still Germany lies in the temperate zone; the flora approximates nearly to that of Great Britain, and the gardens and hot-houses are in no way superior to our own. It rarely enters into the calculations of a young graduate that a journey to the tropics is a possible alternative to the German pilgrimage; yet a circular recently issued by Dr. Treub, the well-known Director of the Botanical Garden at Buitenzorg, in Java, shows us that a visit of six months to the island is well within the range of any man who has 200*l.* to spend upon it. It is true that this expense is decidedly greater than that of living for six months in a German University town, but the advantages are correspondingly greater. In the first place, a tropical vegetation offers ample opportunities for research, especially in the branches of morphology and anatomy; in proof of this it is sufficient to turn over the pages of the *Annales du Jardin botanique de Buitenzorg*, and note the valuable results there detailed, chiefly from the pen of Dr. Treub himself; secondly, the Government of the Dutch Indies has recently placed suitable buildings at the disposal of the Director, who finds that he now has accommodation in his laboratory for four foreign investigators to work simultaneously; again, in the person of Dr. Treub, who, it may be mentioned, is a proficient in the English language, there is constantly present at Buitenzorg one of the first investigators of our time. In his circular Dr. Treub combats the idea which most of us would probably entertain, that Buitenzorg, being in the tropics, is necessarily unhealthy: he states that, though he will not pretend that a stranger coming to stay for four or five months cannot possibly fall ill, still the chances of contracting disease during that time are not notably greater than if one stayed at home or travelled on the continent of Europe. He recommends the period between October and April as the best, both as regards health, comfort, and the vegetation. Here is an opportunity the like of which has perhaps never before been offered to students, and one which can best be embraced by those who have not yet assumed the yoke of regular employment.

These facilities for botanical research in a tropical climate, thus offered freely to strangers by the Dutch, naturally suggest to the English mind that with all our colonies we have at present little of a like nature to offer: we have in our gardens at Calcutta and Peradeniya as good chances of establishing laboratories for botanical research as the Dutch had at Buitenzorg. Prof. Haeckel's interesting account of his recent tour in Ceylon, and of his visit to Peradeniya, gives some idea of the scope there would be for a young botanist to carry on morphological and anatomical work. In the sphere of thallophytic botany Mr. H. M. Ward has already shown that a lengthened stay in the tropics may lead to the attainment of very valuable results.

But without going so far afield as the tropics, and at a decidedly less cost than such a journey would entail, plenty of scope may be found for satisfying the desire to investigate. Thus at the well-known marine biological station at Naples, the tables which are habitually occupied by zoologists might well be applied for by botanists: the numerous botanical memoirs issued from this institution by continental observers show that the institute of Dr. Dohrn is well adapted for the investigation of marine algæ as well as of marine animals.

A second marine station, devoted more particularly to the study of botany, is that at Antibes, now in the possession of the French Government; it was formerly the private residence of M. Thuret, to whose researches, in conjunction with M. Bornet, we owe so much of our knowledge of the reproductive processes of marine algæ. Being compelled, for the sake of his health, to pass the winter months in the south, M. Gustave Thuret chose the beautiful promontory of Antibes for his residence. He laid out the grounds surrounding his villa as a botanic garden, collecting together many rare and beautiful plants; at the same time, while attending to the collection and correct identification of terrestrial forms, he availed himself of the opportunity presented by residence on the coast to apply himself with vigour to those researches on marine algæ with which his name will always be connected. On his death in 1875, Mme. Henri Thuret, desiring that the valuable collections of her brother-in-law should not be dispersed, bought the property for a sum of 200,000 francs, and presented it to the nation, the State undertaking the expenses of its maintenance. M. Naudin was appointed as director of the new institution. It is understood that on suitable application being made, foreigners can obtain admission to the laboratories of the Villa Thuret, which offer exceptional opportunities for the study both of marine and terrestrial forms.

However great the advantage may be of visiting countries of a climate different from our own, it is far from being necessary for an English student to leave his own country in order to satisfy his desire for research. The methods in use in the botanical laboratory are now taught with precision in our Universities; any student who has passed his final examination in the first class should be in a position to conduct a research successfully if he has in him the necessary mental qualities. To such a man the resources of the Royal Gardens at Kew are a real mine which shows no sign of exhaustion. Not only may an investigator obtain access to the unrivalled collections, both living and dry, of the Royal Gardens, but since Kew is in constant communication with distant countries, materials for completing a research may often be obtained which could scarcely be accessible in any other way. Through the munificence of the late Mr. Jodrell, a well-appointed laboratory has been erected in the Gardens, with the express object of encouraging research.

Lastly, it must be admitted that the poverty of our efforts in recent years to investigate the marine algæ of our coasts is little short of a disgrace to us as a maritime nation. Even our commonest sea-weeds are as yet but understood that they would well repay a careful investigation. Work on the sea-coast must for the present depend upon individual enterprise; but we may hope that shortly, when the Marine Biological Association has a fixed abode, botanists may be found ready to make proper use of the opportunities which they will then enjoy.

In view of the constantly increasing bulk of botanical publications, which may be taken as an index of a great increase in activity of research, it may be thought that it is more difficult at the present day to strike out original line than at earlier periods in the development of the science. But, against this great increase of

wledge we must set the more systematic training to
ch students are subjected before they are expected to
e an independent line; secondly, the new methods of
tment and new points of view which now succeed one
ther more rapidly than at any previous time; and,
dly, the very greatly increased facilities for research on
spot in foreign countries. When it is remembered how
y of our most prominent men started their careers as
ellers, the importance of the third of the above con-
rations will be valued as it ought to be. Those who
best able to appreciate the position of anatomical and
siological botany would probably be the first to agree
the opportunities for research in these branches,
er in foreign lands or at home, are, at the present
nent, better than they have been at any former period
ne history of the science. If the botanical students
he present day content themselves with devoting their
and energy to working out small and uninteresting
ils, it is their own poverty of imagination and want
nterprise that are to blame. F. O. B.

MOLECULAR DYNAMICS[1]

HAVE placed the three titles above this article not because I intend to deal with more than the last, but use they all deal with the same matter, and show how h the author's attention was directed to the subject ng his three months' sojourn in America. The ence at the Baltimore lectures consisted chiefly of erican professors, and a few English men of science nded a larger or smaller number of the lectures. peculation was rife as to the probable character of the res, and there was a general feeling that vortex on would be largely dealt with. This, however, was so. The course of twenty lectures was confined to vave theory of light, largely dealing with the diffi- es of that theory. The published lectures are not ed, but "jelligraphed," as Sir William Thomson d say. The number of copies is extremely limited, are of unique interest, being reproduced from the -hand notes taken at the lectures. Every one who vs how suggestive Sir William's lectures are and how e his mind is in bringing illustrative digressions to on the topic in hand, will expect these verbatim s to be a rare treasure. Nor will he be disappointed. Hathaway, the reporter, has the unusual combination eing an expert stenographist, a skilful mathematician, a clear and distinct caligraphist. His notes contain erous errors, such as are unavoidable in such an rtaking, but, viewed as a whole, his work is almost a el.

he lectures treated of three branches of the subject: he propagation of a disturbance through an elastic um; (2) the character of molecular vibration; and he influence of molecules on the propagation of waves. s lecture generally dealt with two of these branches, between the two parts of the lecture Sir William among his audience and had some conversation them. It was ever his object to discard the profes- l attitude and give his lectures the aspect of confer- s. Discussion did not end in the lecture-room, and hree weeks at Baltimore were like one long confer- guided by the master mind. It is not surprising at the end of that time there was a genuine feeling dness at parting on the part of teacher and taught

e part of the lectures dealing with the propagation elastic disturbance could not be expected to contain much novelty, but it was treated in so novel a manner and from so purely a physical point of view, that it could not but be instructive. Many of the old supporters of the theory dealt with it purely from a mathematical point of view. They treated the problem as a mathematical exercise, and did not hesitate to make unwarranted assumptions to produce pretty formulas or simple solutions. Even such men as Weber (in his "Theory of Magnetism") and Green (in his "Wave Theory") have been guilty of this practice. Sir William Thomson never made any but physical assumptions, and these were made for reasons given. Rather than make a meaningless mathematical assumption he would prefer to burden his formulas with undetermined quantities, and even, if unable to reach the final solution, would rejoice in the richness of the formulas, which showed a potentiality of overcoming many difficulties. He does not always commend Rankine's mathematics, but he says this for him at p. 185: "Rankine did a great deal to cure the mathematical disease of *aphasia* from which we suffered so long. Faraday did most. The old mathematicians used neither diagrams to help people to understand their work, nor words to express their ideas. It was formulas, and formulas alone. Faraday was a great reformer in that respect with his language of 'lines of force,' &c. Rankine was splendid in his vigour and in the grandeur of his Greek derivations." This refers to Rankine's nomenclature of different kinds of moduluses and their reciprocals—*e.g. plagiostatic, thlipsinomic*, &c.

The first lecture is a summary of what is to come, and is partly historical. The difficulties in the way of accepting the wave theory of light are clearly pointed out. These are four in number.

First Difficulty: Dispersion.—The difficulty is to explain how velocity of propagation depends on period of vibration. Two explanations have been offered, that of Cauchy and that of Helmholtz. He does not delay much with Cauchy, who ascribed it to heterogeneousness. He prefers Helmholtz, who ascribes it to a compound structure of material molecules, which gives them a natural period of vibration. The one explanation has relation to wave-length, the other to period of vibration. The latter, he thinks, falls in better with results of spectrum analysis, &c. A great portion of the lectures is devoted to expanding the notion of Helmholtz. The space occupied by a molecule must be filled with a substance differing from the ether either in rigidity or in density, or both. Lord Rayleigh has taken in hand this question in his researches on blue sky, and it seems that a variation of density is the principal or only effective cause. With respect to the new (Helmholtz-Thomson) spring and shell molecule, he says, "It seems to me that there must be something in this, that this, as a symbol, is certainly not an hypothesis, but a certainty."

Second Difficulty: the Ether.—He makes short work of the difficulty of reconciling almost perfect rigidity with almost perfect mobility. It is merely a matter of time. You can make a tuning-fork of Burgundy pitch when the period is a small fraction of a second, but a bullet will pass clean through several inches of it in six months. The ether may be highly elastic for vibrations executed in the 100 or 1600 million millionth of a second, but highly mobile to bodies going through it at the rate of twenty miles a second.

Third Difficulty: Refraction and Reflection.—Theoretical equations agree qualitatively with facts, but there are serious discordances when we come to quantitative measurements. Especially is this the case in the completeness of extinction of the ray polarised by reflection.

Fourth Difficulty: Double Refraction.—It is found that when the medium is displaced during wave-propagation in a double refracting crystal, the return force must depend on the direction of vibration, not on the plane of distortion, as all elastic theories indicate. Rankine and

[1] On Molecules," the Presidential Address to Section A of the British ation, August, 1884, by Sir William Thomson.
e Wave Theory of Light," a Lecture delivered by Sir William on at Philadelphia on Sept. 29, 1884, published in NATURE, vol. xxxi.
tures on Molecular Dynamics," by Sir William Thomson, Johns University, October, 1884.

Rayleigh independently invented unequally loaded molecules which overcome the difficulty, but give a wave surface different from Huyghens', and Stokes has proved experimentally that Huyghens' construction is very accurate. Hence this way of escape is denied to us.

In treating of the propagation of waves in an isotropic (and later in an aeolotropic) medium, methods of Thomson and Tait's Natural Philosophy, and his own article, "Elasticity," in the "Encyclopædia Britannica," are used; $a\,b\,c$ are distortions about Ox, Oy, and Oz, $e\,f\,g$ are dilatations along Ox, Oy, Oz. The equation of the energy E is a quadratic in $a\,b\,c\,e\,f\,g$, containing twenty-one coefficients, some of which are annulled by isotropy.

If

$$P = \frac{dE}{da},\ Q = \frac{dE}{df},\ R = \frac{dE}{dg};$$

$$S = \frac{dE}{de},\ T = \frac{dE}{db},\ U = \frac{dE}{dc},$$

and if ρ be the density, and ξ a displacement along Ox, we obtain the equation

$$\rho\frac{d^2\xi}{dt^2} = \frac{dP}{dx} + \frac{dU}{dy} + \frac{dT}{dz}.$$

Moreover, if n be the rigidity modulus, k the bulk modulus, δ the cubic dilatation, and $m = k + \frac{4}{3}n$, we have

$$P = (m - n)\,\delta,$$

$$T = n\left(\frac{d\xi}{dz} + \frac{d\zeta}{dx}\right),$$

with similar expressions for Q, R, S, U.

Thence he shows that the equation

$$\rho\frac{d^2\xi}{dt^2} = m\frac{d\delta}{dx} + n\nabla^2\xi,$$

(with the condition $\frac{du}{dx} + \frac{dv}{dy} + \frac{dw}{dz} = 0$ in an incompressible substance), contains every possible solution, and he proceeds to discuss special cases of the general solution which may be true of waves propagated by molecules through the ether. Here his desire for physical conceptions appears, and his hatred of mathematical *asphasia*. He considers the case of a ball moving to and fro, of a ball twisting about an axis, of a globe becoming alternately prolate and oblate, of a rod twisted in opposite directions at the two ends, and of the Thomson-Helmholtz molecule which is a heavy mass connected by massless springs with a massless inclosing shell, or there may be several shells inclosing each other, connected by springs with a dense mass in the centre (far more dense than the ether).

Here he discusses the manner in which a molecule may be supposed to give off its vibrations to the ether. Does it gradually increase in intensity and gradually die out, or how does it act? Here is what he says on this much-neglected point at p. 94:—

"The kind of thing that the luminous vibrator consists in seems to me to be a sudden initiation of a set of vibrations and a sequence of vibrations from that initiation which will naturally become of smaller and smaller amplitude. . . . Why a sudden start? Because I believe that the light of the natural flame or of the arc light or of any other known source of light must be the result of sudden shocks from a number of vibrators. Take the light obtained by striking two quartz pebbles together. You have all seen that. There is one of the very simplest sources of light. . . . What sort of a thing can the light be that proceeds from striking two quartz pebbles together? Under what circumstances can we conceive a group of waves of light to begin gradually and to end gradually? You know what takes place in the excitation of a fiddle-string or a tuning-fork by a bow. The vibrations gradually get up from zero to a maximum, and then, when you take the bow off, gradually subside. I cannot see anything like that in the source of light. On the contrary, it seems to me to be all shocks—a sudden beginning and gradual subsidence."

The light coming from a single shock is, of course, polarised always in the same direction. Sellmeier's deductions from Fizeau's experiment shows that there is no serious fading in 50,000 vibrations. Helmholtz introduces viscous terms which absorb the energy and might prevent the possibility of 50,000 vibrations from one shock. That is a retrograde step. Absorption can be explained without viscous terms.

Such speculations, when coming from one of less grasp of physical facts, would attract but little attention. But here all kinds of useful suggestions are continually thrown out for experiment and for hypotheses. He is striving to get at the physical meaning of radiation, absorption, anomalous dispersion, fluorescence, and phosphorescence, and here is what he says on some of these points at p. 90:—

"But there are cases in which we have that tremendous jangling, and that is in the fluorescence of such a thing as uranium glass, which lasts for several seconds after the exciting light is taken away, and then again in phosphorescence that lasts for hours and days. There have been exceedingly interesting beginnings in the way of experiments already made, but I think no one has found what the initial refraction is exactly the same as permanent refraction. For this purpose we might use Becquerel's phosphoroscope, or we might take such an appliance as Professor Michaelson has been using for light, and get something enormously more searching than Becquerel's phosphoroscope, and try whether, in the first hundredth of a second there is any indication of a different wave-velocity from that which you would have when white light passes continuously in the usual manner of refraction. If any of the methods employed for ascertaining the velocity of light in a transparent body . . . we apply a test for an instantaneous refraction, I have no doubt we shall get negative results, but yet properties of ultimate importance. We might take bodies in which, like uranium glass, the phosphorescence lasts only a few seconds; and then, again, bodies in which phosphorescence lasts for minutes or hours. With some of these we should have anomalous dispersion, gradually fading away after a time. I should think that by experimenting, and so on, we should have some very interesting results of this kind."

In his mathematics he suppresses the condensational wave, and, in doing so, makes reference to the electro-magnetic theory of light, which, he thinks, has added nothing to our physical conceptions of the ether. In treating, further on, of reflection and refraction, he speaks a great deal of the pressural wave, which many authors have called a condensational wave. I find that in some points my notes are fuller than the reporter's. I must find there the following characteristic passage about the pressural wave:—"People have tried to muddle [illegible]. The pressural wave has been the difficulty. Cats [illegible] starved the animal, M'Cullagh and Neumann didn't believe of its existence, Haughton put it in an Irish car and it wouldn't go, Green and Rayleigh treated it according to its merits."

With regard to the possibility of a condensational wave and to the electro-magnetic theory of light, we find at pp. 40-41:—

"We ignore this condensational wave in the theory of light. We are sure that its energy, at all events, if it is not null, is very small in comparison with the tremendous vibrations we are dealing with. But to say that it is absolutely null would be an assumption we have no right to make. When we look through the little universe that we know, and think of the transmission of electric force and of the transmission of magnetic force, and of the transmission of light, we have no right to assume that there is not something else that our philosophy has

ream of. We have no right to assume that there not be condensational vibration in the luminiferous . We only do know that any vibrations of this kind h are excited by the reflection and refraction of light certainly of very small energy compared with the gy of the light from which they proceed. The fact e case as regards reflection and refraction is this: unless the luminiferous ether is absolutely incom-ible, the reflection and refraction of light must gene- give rise to waves of condensation. Waves of rtion may exist without waves of condensation, but s of distortion cannot be reflected at the boundary ce between two mediums without exciting in each ium a wave of condensation. When we come to the ct of reflection and refraction we shall see how to with these condensational waves, and find how easy to get quit of them by supposing the medium in-pressible. But it is always to be kept in mind to be ined into: Are there or are there not very small unts of condensational waves generated in reflection refraction; and may, after all, the electric force not nd on the waves of condensation? Suppose that ave at any place in air, or in luminiferous ether, a that, through some action we need not describe, which is conceivable, is alternately positively and tively electrified: may it not be that this will be the e of condensational waves?" It is then supposed two spherical conductors are connected to the inals of an alternating dynamo machine, and the tation proceeds:—

It is perfectly certain, if we turn the machine slowly, in the neighbourhood of the conductors we will have nately positively and negatively electrified elements reversals perhaps two or three hundred per second ime, without a gradual transition from negative ugh zero to positive, and the same thing all through e; and we can tell exactly what is the potential at point. Now, does any one believe that, if that revo-n was made fast enough, the electrostatic law would w? Every one believes that, if that process be con-ed fast enough several million times, or millions of ion times per second, we should be far from fulfilling electrostatic law in the electrification of the air in the hbourhood. It is absolutely certain that such an on as that going on would give rise to electrical es. Now it does seem probable to me that electrical es are condensational waves in luminiferous ether, probably it would be that the propagation of these es would be enormously faster than the propagation ordinary light waves. I am quite conscious, when aking of this, of what has been done in the so-called tro-magnetic theory of light. I know the propagation lectric impulse along an insulated wire surrounded by ta-percha, which I worked out myself about the year 4, and in which I found a velocity comparable with velocity of light. . . . That is a very different case n this, and I have waited in vain to see how we can any justification of the way of putting it in the so-ed electro-magnetic theory of light."

n those parts of the lectures which deal with wave pagation in an isotropic medium, by far the most resting parts are those which treat of the conditions ounding surfaces, whether these surfaces be reflecting refracting surfaces or surfaces of radiating molecules, surfaces of absorbing molecules. Lord Rayleigh's in-tigations and his own on the likelihood of the density the rigidity of the substance composing a molecule ering from that of the ether are also full of interest

[redacted] this part of the subject has been thoroughly fore, but here the treatment is so original, so suggestive, and I need hardly say that of lectures is so pregnant with useful who reads this part will be well

Having now roughly indicated the novel points and the general mode of treatment of the problem in *molar* dynamics, I propose in the next notice to give some account of the problem in *molecular* dynamics, which occupied half of the time. GEORGE FORBES

(*To be continued.*)

THE LONG DURATIONS OF METEORIC RADIANT POINTS

IT is unfortunate that the observation of shooting stars is associated with difficulties of no common order. The very large number of distinct showers visible at the same epoch, their extremely attenuated character, and the many impediments to accurate determinations of the flights of the individual shooting stars proceeding from them, exercise an unfavourable influence on the work and deter many observers from grappling with a subject which is admittedly beset with such perplexing details. Apart from this, there exists the great necessity for observations to be sustained during the whole night, and this is rarely practicable either by amateur or professional astronomers, who generally have other important work in hand. In fact, meteoric astronomy requires the almost exclusive attention of the observer, and must be closely pursued for a long period of time if anything like comprehensive results are to be obtained. The voids occasioned either by moonlight or cloudy weather in a short series of observations are only to be filled up by prolonged watches extended over many consecutive years.

The long visible duration of a large number of radiant points of shooting stars is, it must be confessed, a fact which defies satisfactory explanation. The ingenious theory which had attributed to meteor streams an identity with cometary orbits, required that the visibility of such streams should be of very brief character, though in the case of an abnormally wide system or of a shower directed from a point near the earth's apex the duration might be longer than usual, but the radiant point could not maintain a perfectly fixed position amongst the stars. This general view of the subject is, however, not accordant with the results of recent observations, for while there are undoubtedly some cometary showers which display all the peculiarities taught by theory, there are many other streams which continue visible for several months and retain a stationary position in the firmament. It is evident therefore that these streams are presented to us under totally different circumstances as regards orbit to the true planetary showers, and are amenable to conditions and laws which form a problem the solution of which is arrested by no ordinary difficulties.

The multiplicity of streams would naturally originate a false appearance of long duration in certain radiant points, but observations of very precise character would soon show that the point of radiation, as successively determined, differed considerably, being not, in fact, confined absolutely to the same point in the sky. But it is now proved that there are no differences, other than those introduced by small unavoidable errors of observation, in the centres from which shooting stars continue to fall during several months. Indeed, it seems a probable inference from the observations that some showers exist all the year round, though not visible during the epoch when they are very near to the sun.

That such long enduring radiants of meteors can have a community of origin and belong to physically associated streams in the same degree as the true cometary meteor showers is very difficult to understand. But the fixity of the radiant over so long an interval would yet seem to indicate some bond of close affinity existing between them. At any rate we have no reason to suppose that a large number of showers, distinct in themselves, can occur consecutively from the same points of the sky owing to a common peculiarity of grouping.

At intervals of six months the earth's motion in space is in exactly opposite directions, and yet these streams of meteors enter the atmosphere from the same apparent radiants. Evidently therefore the meteoric particles, which individually move in parallel flights, are travelling independent of solar attraction and are presented to us under a totally different aspect to the cometary showers the phenomena of which are clearly understood.

If meteoric streams of great width are encountered by the earth as the result of the sun's proper motion in space then it would appear that to give the phenomena of stationary radiants they must move with enormous velocities. This is not borne out by the observations, for the meteors of these long-enduring streams exhibit appearances similar to what is generally observed in the meteors from the cometary showers. The farther the radiant is removed from the earth's apex the slower become the motions of the meteors, they lose the streak-generating capacity, and their colour changes from white to yellow or red, indicating a lower degree of incandescence as a result of a less violent friction with the air. There are exceptions, however, for the meteors whose radiants retain a velocity much greater than that theoretically assigned.

There is a very pressing need for further observations specially directed to the visible trajectories of shooting stars. The apparent motions of the objects belonging to a stream depend upon several factors which are very liable to originate discordances. The particles near the radiants move slowly in short paths owing to foreshortening, and when the radiant is near the horizon the flights are longer and more gradual when it has reached a considerable altitude. The Geminids of December, for instance, appear very slow in the early hours of the evening, but in the morning swift, diving courses would lead the observer to assign them to an entirely separate family were it not that the radiant occupies an identical place to that of the

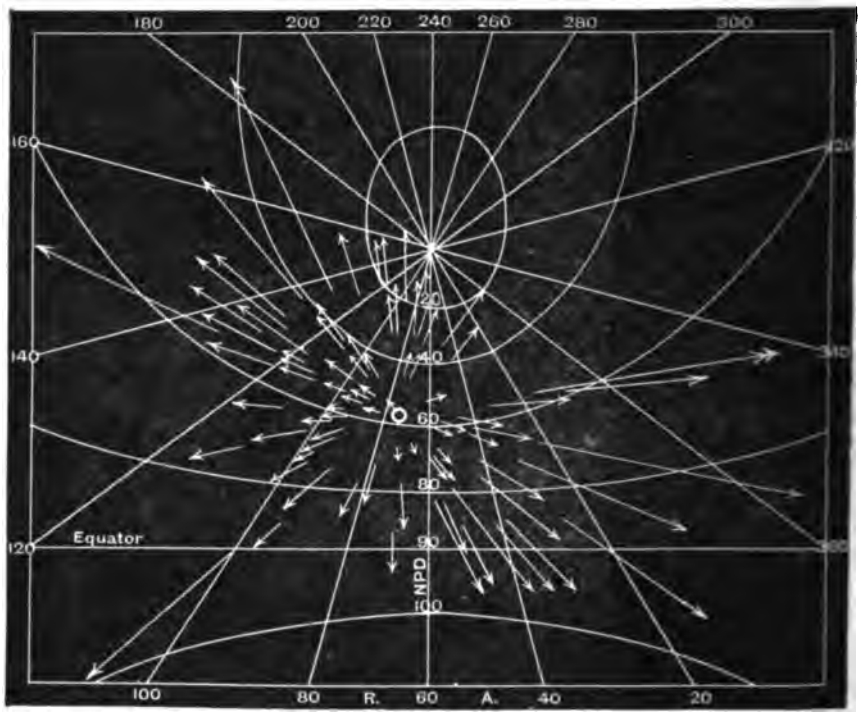

FIG. 1.

from the slower meteors recorded several hours before. Some showers also doubtless furnish meteors which become igneous at greater distances than others and more relatively slower than those belonging to streams formed of materials not so readily combustible. Moreover the specific gravity of the particles of different systems probably varies to some extent, and their individual forms may not always coincide, so that the effects of atmospheric resistance must necessarily introduce peculiarities in the observed flights.

The idea occurred to me that these long-enduring radiants must result from terrestrial meteor streams, *i.e.* streams revolving around the earth in an excentric orbit with perigee near the outer limits of the atmosphere. If streams of this character existed and were closing in upon the earth we should have the phenomenary radiants. And the fact of their closing would be rendered possible on the assumption ing medium (similar to that affecting the moti net), or that at each return to perigee th countered the tenuous outer region of the atmo which, though not sufficiently dense to render incandescent, would slightly diminish their velo thus bring about a contraction of the orbit. are difficulties to the adoption of such views, one is that the meteors from such streams would consistency of velocity whatever the relative their radiants with regard to the earth's motion, and this does not accord with the fact vation.

The earth's atmosphere probably extends appreciable degree estimates allow. deduced from mu of minute, telesco exterior to or probable.

wn observations telescopic meteors exceed the more onspicuous class of these bodies in the proportion of bout 40 to 1. Rich showers probably exist only visible ith instrumental means, and certain showers readily erceptible to the naked eye afford little indication of their xistence with telescopic aid. The Geminids may be nked among the latter, for on December 12, 1877, Lewis wift at Rochester, whilst comet seeking during a period f 4½ hours, noticed a large number of naked eye meteors. hey frequently intruded upon his attention in the inter- als when his eye was withdrawn from the telescope, and is estimate of the number visible was 1000 for the whole eriod of his observations. Yet, singularly enough, there as an unusual paucity of telescopic meteors, only two ertainly, and one other suspected, crossing the field of iew of $1\frac{1}{2}^{\circ}$, whereas they are usually of frequent ccurrence.

The observation of meteors, both telescopic and other- ise, especially commends itself to amateurs as an attrac- ve study, requiring no elaborate or expensive instruments. he inconveniences attending such work may soon in reat measure be overcome by patience. In cases where e results are thoroughly reliable we think that even ender observations possess weight and ought to be ncouraged, for such results soon accumulate, and if

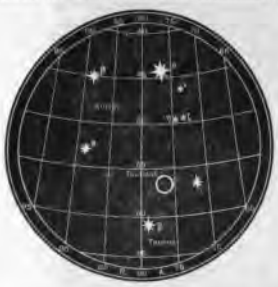

FIG. 2.

owed to extend over several years may be combined d reduced to very satisfactory issues. Or the materials tained by different observers for similar epochs might collected and the radiant points determined from a reful analysis of the path-directions. In every instance, wever, the physical appearances of the meteors ought to fully described and given due weight in fixing the liants. Without these precautions it is impossible to tain reliable positions or to arrange the meteors into nily groups with anything like that precision which is essential feature of the work.

It is earnestly hoped that more enthusiasm may now aroused amongst observers in this interesting depart- nt of astronomy. The question as to the duration of liants and their absolutely fixed position must have an portant bearing on the theory of their origin, and erves much further investigation. The apparently rmittent character of many such streams also deserves ice, as their fluctuations may be regulated by definite iods of short duration. The observations of individual iants should be confined to a few nights only, or when, n the paucity of meteors, it is found necessary to lude results extending over several weeks, the nights greatest intensity should be mentioned. The necessity ts for equal accuracy in deducing the radiant points, n registering the exact directions of flight; in fact, great discrimination and precision are required in details so mutually dependent, so liable to errors, and so full of complications.

One of the most active and at the same time one of the most precise and well-defined cases of long duration is exhibited by a meteor shower in the southern extremity of Auriga and slightly to the north-east of a line connecting the stars ι Aurigæ and β Tauri. It gives the first sign of its existence at the end of July, and thence continues during several ensuing months. The epochs about October 8–15 and November 7 and 20 would appear to represent the most prominent exhibition of this radiant, though there are many other nights during the summer and autumnal months when it may be detected during a prolonged watch. The accompanying diagram (Fig. 1) shows the projected paths of eighty meteors (chiefly observed by myself at Bristol, and selected as being tolerably near the radiant point) recorded during the months of October and November. These paths form only a proportion of the aggregate number seen, but they sufficiently display the singularly precise radiation of this stream. A similar diagram might readily be prepared from the flights recorded in August and September when the convergence of an almost equal number of meteors attest the visibility of the same radiant. Its position relatively to the stars is given in Fig. 2, and it is hoped that observers will endeavour to effect its re-observation. We require further observations particularly during the month of August, when the radiant is very low, until the morning hours, and this doubtless accounts for the rareness of its apparition at that epoch.

W. F. DENNING

NOTES

THOSE who are interested in the South Kensington Museum will be glad to learn that the National Collections belonging to the Science Department have now a prospect of improvement. A Government Committee has lately been appointed to report generally upon them and to consider plans for properly housing them. The Committee consists of gentlemen of high position in various Government Departments; the Chairman is Sir Frederick Bramwell, F.R.S., and Dr. W. Pole, F.R.S., is the Secretary.

THE Prince of Wales, President of the International Inventions Exhibition, has fixed Monday, May 4, for the opening of the Exhibition. Rapid progress is being made in all branches connected with the Exhibition. The large space set apart for machinery in motion is already being filled, whilst preparations for receiving other exhibits are well forward, some of which have arrived at the building. The Aquarium Department is receiving considerable attention, and will form a very attractive feature. The tanks have been thoroughly cleansed and refilled with fresh water, which has been softened and filtered, rendering it bright and pure, fit for the reception of large consignments of fish that will shortly arrive. Lord Onslow has lately presented 1500 exceedingly fine carp to the Aquarium, and a large number of fish indigenous to the Canadian Lakes have also been received for exhibition in the tanks.

THE Royal Society of New South Wales offers its medal and a money prize for the best communication (provided it be of sufficient merit) containing the results of original research or observation upon each of the following subjects:—Series IV. To be sent in not later than May 1, 1885:—No. 13. Anatomy and life-history of the Echidna and Platypus; the Society's Medal and 25*l*. 14. Anatomy and life-history of Molluscs peculiar to Australia; the Society's Medal and 25*l*. 15. The chemical composition of the products from the so-called Kerosene Shale of New South Wales; the Society's Medal and 25*l*. Series V. To be sent in not later than May 1, 1886:—No. 16. On the chemistry of the Australian gums and resins; the

Society's Medal and 25*l*. 17. On the tin deposits of New South Wales; the Society's Medal and 25*l*. 18. On the iron-ore deposits of New South Wales; the Society's Medal and 25*l*. 19. List of the marine fauna of Port Jackson, with descriptive notes—as to habits, distribution, &c.; the Society's Medal and 25*l*. Series VI. To be sent in not later than May 1, 1887:—No. 20. On the silver-ore deposits of New South Wales; the Society's Medal and 25*l*. 21. Origin and mode of occurrence of gold-bearing veins and of the associated minerals; the Society's Medal and 25*l*. 22. Influence of the Australian climate in producing modifications of diseases; the Society's Medal and 25*l*. 23. On the Infusoria peculiar to Australia; the Society's Medal and 25*l*. The competition is in no way confined to members of the Society nor to residents in Australia, but is open to all without any restriction whatever, excepting that a prize will not be awarded to a member of the Council for the time being; neither will an award be made for a mere compilation, however meritorious in its way—the communication, to be successful, must be either wholly or in part the result of original observation or research on the part of the contributor. The successful papers will be published in the Society's annual volume. Fifty reprint copies will be furnished to the author free of expense. Competitors are requested to write upon foolscap paper, on one side only. A motto must be used instead of the writer's name, and each paper must be accompanied by a sealed envelope bearing the motto outside and containing the writer's name and address inside. All communications to be addressed to the honorary secretaries, A. Liversidge and A. Leibius.

A LECTURE on "Cholera, what it is, and how it may be guarded against," will be given by Prof. Burdon-Sanderson at Toynbee Hall, 28, Commercial Street, E., on Thursday, March 26, at 8.15 p.m.

A MEETING of scientific men was held on Saturday at the University College, Liverpool, at which it was resolved to prepare a scheme for investigating the marine fauna of the neighbouring seas, so that a commencement of the work might be made during the ensuing summer. Prof. Herdman had the organising and details entrusted to him.

THE Duke of Westminster and the Committee of the Sunday Society have issued invitations to a National Conference with authorities and officers of museums, art galleries, and libraries which have been open in the United Kingdom on Sundays. The Conference has been called specially for the purpose of directing the attention of Parliament to the results which have attended the Sunday opening of museums, art galleries, and libraries in the United Kingdom, and it is expected that representatives will be present from each of these institutions. The Conference will assemble at St. James's Hall, on Wednesday, March 25, at half past two, and the proceedings will commence at three o'clock precisely.

AT the meeting of the Society of Arts on Wednesday, the 25th inst., Mr. A. J. Ellis will read a paper on the "Musical Scales of Various Nations." The paper will be illustrated by playing the scales, and occasionally strains on properly tuned instruments, and will form a continuation of the paper [on the "History of Musical Pitch," read by Mr. Ellis before the Society in 1880. It is the result mainly of an examination of native instruments and performers, by which the exact pitch of the notes used was determined by Mr. Ellis and Mr. Hipkins, and will exhibit the scales in use in ancient Greece, in Arabia, India, Java, China, Japan, and other countries. The chair will be taken by Sir Frederick Abel, the Chairman of Council of the Society.

THE Committee of the Saltpetre Producers' Association, on the west coast of South America (Comité Salitrero at Iquique, Chili) offers 1000*l*. in prizes for essays on the use of nitrate of soda as manure. Of this amount (1) a prize of 500*l*. will be awarded for the best popular essay showing the importance of nitrate of soda as a manure, and the best mode of its employment. The essay, in its theoretical part, is to treat of the effect of nitrate of soda on vegetation, as compared with other manures containing nitrogen, and should exhibit the present state of knowledge on this point. In its practical part the essay is to give directions for the use of nitrate of soda in the various conditions of plant-culture. References and quotations, and purely scientific explanations, if necessary, are to appear in notes. The essay may be written in English, German (Italic character), or French. The writing must be distinct, and on one side of the paper only. It is desired that the length of the essay may not exceed six sheets of printed octavo. Each manuscript is to be signed with a motto; the name and address of the author is to be given in a sealed envelope bearing the motto outside. The essays are to be sent on or before October 1, 1885, to any of the undermentioned judges. (2) A prize of 500*l*. will be awarded for the best essay treating of the same subjects on the basis of new experimental researches, made by the author himself. The essays must fulfil the conditions already mentioned. They may be sent to any of the judges on or before January 1, 1887. The Committee of judges consists of the following agricultural chemists:—Germany: Prof. Paul Wagner, Director of the Agricultural Station at Darmstadt. England: Mr. R. Warington, Agricultural Laboratory, Rothamsted, St. Albans, Herts. United States of America: vacant. France: Prof. L. Grandeau, Director of the Agricultural Station, and Dean of the Faculty of Natural Philosophy at Nancy. Belgium: Prof. Petermann, Director of the Royal Agricultural Station at Gembloux. Holland: Prof. Adolf Meyer, Director of the Agricultural Station of the State at Wageningen. Russia: Prof. L. Thoms, Director of the Agricultural Station at the Polytechnical Institution at Riga. If none of the essays received should thoroughly satisfy the committee of judges, they are authorised to award inferior prizes of not less than 150*l*. each. Any essay for which a prize is awarded becomes the absolute property of the Saltpetre Producers' Association at Iquique, which also reserves to itself the right of translation into other languages.

IN his series of lectures on electricity, M. Becquerel *fils* exhibited at the Conservatoire des Arts et Métiers a loud-speaking telephone, which was heard without difficulty throughout the amphitheatre. This will be one of the attractions of the forthcoming electrical exhibition at the Observatoire. The halls will be lighted by a new lamp constructed by MM. Breguet and Co.

THE January number of the *Melbourne Review* contains a very interesting article on the climatic vicissitudes of Victoria, by Mr. G. S. Griffiths. Referring to the researches of Baron von Müller, the writer says that that learned botanist has discovered striking testimony to the occurrence of rapid climatic changes in Australia. First he found that during the older Pliocene period the Australian flora was lauraceous—plants of the warmth-loving laurel family predominating. In the newer Pliocene deposits these laurels have been swept away, and are replaced by a meliaceous flora and by plants of a still more tropical character. Once more an active vegetation disappears, and in its stead the myrtle family, with its characteristic eucalypts, overspreads the whole land, and still keeps possession. What great climatic vicissitudes (Mr. Griffiths asks) could sweep a region of a whole suit of vegetation and repeat the act twice within a brief period? He thinks this evidence to be strongly corroborative of the occurrence of interglacial periods. The

however, other facts. The pepper plant (*Drimys amarilina*) native of the colder regions of the globe. When the Glacial ch set in and a chilly temperature advanced to the equator lf, this plant marched forward with it in the same regions, en the interglacial warm period came on the cold temperature xed; but wherever the pepper plant had access to lofty ntains it retreated to their cold peaks, and so secured itself panently in its new home. Then it died out on the hot ns, and thus Mr. Griffiths explains its existence upon the y ranges of New Guinea and Borneo, but nowhere else until get far down into the colder regions of the southern hemi-ere—its natural habitat. In the same manner cold-loving opean plants crossed the hot tropics, unknown ages since, probably at the same epoch, and established themselves in stralia; and so, when botanists in exploring the Australian ntains climbed to an altitude of 5000 feet, they met thirty-t species of European plants, isolated from their fellows, thousands of leagues from their home.

HE Russian Government has ordered from a Paris balloon ory two elongated silk balloons, in order to experiment on r direction by electricity. The Italian Government has also ered two silk balloons equipped with telephones, &c., for ive ascents.

O the *Astronomische Nachrichten*, Nos. 2651-52, Herr von ard contributes an elaborate paper on the periodicity of the nges observed in the spectrum of *β* Lyræ during the year . The observations of the previous year had already deter-ct changes in the intensity of the bright bands, which could be accounted for by mere atmospheric influences. Since thirty fresh observations have enabled the author to follow ugh successive periods the shiftings of the bands D_3 from an st brilliant intensity to their total disappearance. He was nted by the unfavourable atmospheric conditions from de-ining the duration of the several periods, which however ed to average not more than seven days. The hydrogen and also very probably those of the red, although more ant, also seem subject to periodical change. The spectro-ic phenomenon is of such a remarkable and unique character observers are urged to direct their attention to this highly esting star, with a view to a more accurate determination periodicity. Appended to the paper is a brief summary of hirty observations taken at intervals from February 18 to mber 17 of last year. Of these the following may be d as bearing on the short duration of the periodic changes:— 13, D_3 of almost dazzling brightness; July 17, D_3 very ; September 17, D_3 scarcely perceptible; September 24, gain brilliant; November 1, D_3 invisible; November 5, ight.

important point in connection with recent seismic igation in Japan which does not yet appear to have noticed in this country, is the various intensities ne same shock and of different shocks at different . One place appears more subject to earthquakes another place which may be near at hand, and to ore violently affected than the latter by an earthquake visits both. Thus, with similar instruments placed at the rs of a triangle having sides about 800 feet long, Prof. has obtained conclusive evidence that, while at one there might be sufficient motion to shatter a building, e other corners the disturbance would be trivial. In st severe shock by which the capital of Japan was visited, chimneys of the British Legation were shaken so severely ney had to be rebuilt, but the Russian Legation, a building ch the same character a mile away, suffered no appreciable ge. If in further investigation it turns out that certain portions of the same earthquake district are comparatively free from violent shocks, while the force of the earthquakes are concentrated in certain others, then seismic surveys would appear an indispensable pre-requisite of building in earthquake countries. A residence in "a desirable situation" would in that case mean, not one commanding a good view, or close to the station, church, and post-office, or convenient for a pack of hounds, but one built on an oasis unsympathetic to earthquakes, and which remains still and secure while its neighbours are being tossed about and destroyed by seismic forces.

THE Sixth Circular of Information of the United States Bureau of Education for 1884, compiled by Miss Annie T. Smith, a Member of the Office, is a digest of the information gained there on the subject of rural schools. It is hardly necessary to refer here to the difficulty of a thinly populated country like America—viz. the smallness of the schools, and hence, in defiance of State laws, the smallness of teachers' pay and teachers' qualifications. High authorities are here cited as to the ease with which much valuable information might be imparted to many such teachers who sorely need it. Good technical rules accordingly for teachers in any country, and a list of about eighty books bearing upon education and desirable for a schoolmaster's library are here given. The Circular records the eager desire for new ideas on the subject of elementary instruction manifest in all countries; and after quoting the highest English and American authorities on the subject, it gives a *résumé* of some recent publications of the Belgian and French Governments. The principal result of it all is to insist upon the great value of general object-lessons; for which purpose, moreover, French schools are cited as being provided with specimens of the materials used in the trades of the neighbourhood: to urge the teaching of geography first from the nearest surrounding view, and *then* from the map which has thus been made intelligible; of elementary arithmetic also by objects. The way in which, in agricultural districts, this object-learning goes on side by side with book-learning, especially in the cases of the youngest boys whose time is divided between school and labour, makes it a familiar phrase in America that "our brightest boys come from the country."

IN the report of the Temple Observatory at Rugby for 1884, Mr. Seabroke, the Honorary Curator, reports that the original work done during the past year consisted of the measurement of positions and distances of double stars, in continuation of that of former years. 264 complete measures of 108 stars were taken. The observations of double stars of the last four years have, it is stated, been presented to the Royal Astronomical Society, and ordered to be printed in the *Memoirs*. They number about 900 complete measures. A new list of stars for measurement in coming years has been prepared by Mr. Seabroke, with the assistance of Mr. C. H. Hodges. Some few measurements have also been made of the motion of stars in the line of sight with the spectroscope on the reflector.

THE decreasing tendency of the lobster fishery in America is becoming so marked that the United States Fisheries Commission is instituting inquiries into the causes operating against it. It is intended to investigate all points connected with the natural history of the species, the condition of the fishery grounds, &c., in order to arrive at a satisfactory conclusion on the subject.

THE Council of the National Fish Culture Association have decided to form an ichthyological library containing works of every description on the subject of our fish and fisheries, their culture and development.

WE have received separate reprints of the following papers read before the Chemical Society:—"On Additive and Com-

densation Compounds of Diketones with Ketones," by Messrs. Japp and Miller, and "On Condensation of Benzil with Ethyl Alcohol," by Dr. Japp and Miss Mary E. Owens.

We have received from Messrs. Lancaster and Son, of Birmingham, a catalogue of photographic apparatus for dry-plate photography, and a useful illustrated pamphlet, "How to be a Successful Amateur Photographer," by W. J. Lancaster, F.C.S.

The additions to the Zoological Society's Gardens during the past week include a Bonnet Monkey (*Macacus sinicus* ♀) from India, presented by Mrs. Thomas; a Grey Ichneumon (*Herpestes griseus*) from India, a Vulpine Phalanger (*Phalangista vulpina* ♂) from Australia, presented by Mr. J. G. Baxter; a Plantain Squirrel (*Sciurus plantani*) from India, presented by Lieut. A. H. Oliver, R.N.; a Barn Owl (*Strix flammea*), British, presented by Mr. W. P. Clark; a Red-billed Whistling Duck (*Dendrocygna autumnalis*) from South America, presented by Mr. Wm. Boutcher; an Indian Crocodile (*Crocodilus palustris*) from India, presented by Mr. John Murphy; a Common Boa (*Boa constrictor*) from South America, presented by Mr. Allen; an Algerian Tortoise (*Testudo mauritanica*) from North Africa, deposited; a Red-eared Monkey (*Cercopithecus erythrotis* ♂), a Pluto Monkey (*Cercopithecus pluto* ♀), a White-thighed Colobus (*Colobus vellerosus* ♂) from West Africa, a Hairy-nosed Wombat (*Phascolomys latifrons* ♀), a Blood-stained Cockatoo (*Cacatua sanguinea*) from South Australia, purchased; three Long-fronted Gerbilles (*Gerbillus longifrons*), born in the Gardens.

OUR ASTRONOMICAL COLUMN

Tempel's Comet (1867 II.).—M. Raoul Gautier has circulated an ephemeris of this comet, intending to communicate the details of his calculation of the effect of the perturbations of Jupiter during the comet's long continuance in the neighbourhood of the planet in the last revolution to the *Astronomische Nachrichten*. The ensuing perihelion passage is retarded thereby rather more than 148 days: the major-axis of the orbit is considerably increased and the eccentricity diminished. As a consequence the perihelion distance receives a very important augmentation. This result, which could not have been foreseen without at least an approximate determination of the perturbations occasioned by the attraction of Jupiter, materially diminishes the chances of observing the comet during the present year, and indeed in future years, so long as the elements do not undergo considerable change. M. Gautier finds that the perihelion passage is delayed until September 25, but that the nearest approach of the comet to the earth occurs on March 31, when its distance is 1·51. The maximum theoretical intensity of light which is attained on April 10 is only 0·074 (if expressed in the usual manner); for comparison with this value, it may be remarked that on August 21, when Schmidt last observed the comet for position in that year, perceiving it, as he says, only "blickweise," the intensity of light was 0·21, and at M. Tempel's last observation at Florence on July 8, 1879, it was 0·33. It will therefore be obvious that the observation of the comet in the present year is at least doubtful, but an extract from M. Gautier's ephemeris, applying to the next period of absence of moonlight, is subjoined:—

At Berlin Midnight

	R.A. h. m. s.	Decl. ° ′	Log. distance from Earth	Sun
April 2 ...	11 55 17 ...	+18 56·3 ...	0·1792 ...	0·3877
4 ...	11 53 44 ...	18 58·2		
6 ...	11 52 14 ...	18 59·1 ...	0·1803 ...	0·3851
8 ...	11 50 47 ...	18 58·9		
10 ...	11 49 24 ...	18 57·7 ...	0·1824 ...	0·3826
12 ...	11 48 5 ...	18 55·3		
14 ...	11 46 52 ...	18 51·8 ...	0·1855 ...	0·3801
16 ...	11 45 43 ...	18 47·2		
18 ...	11 44 40 ...	+18 41·6 ...	0·1894 ...	0·3776

The elements of the orbit are as follows (M. Eq. 1885·0):—

Perihelion passage, 1885, September 25·7649 M.T. at Berlin

Longitude of perihelion	241 26 1·1
,, ascending node	73 28 7·7
Inclination	10 50 2·2
Angle of excentricity	23 53 5·3
Log. semi-axis major	0·54214
Mean daily sidereal motion	545″·3

The perihelion distance in 1867, in which year the comet was first detected by M. Tempel, was 1·564, the earth's mean distance from the sun being taken as unity: the above elements show that at perihelion passage in 1885, this distance will have been increased by perturbation to 2·073. The nearest approach of the comet to the earth's orbit occurs at or very close to perihelion, and it will appear that under the most favourable conditions, with the orbit of 1885, the theoretical intensity cannot exceed one-sixth of the value which it might have reached in the orbit of 1867. At aphelion in the new orbit the comet approaches that of Jupiter within 0·17.

The Variable Star Mira Ceti.—Mr. Knott, who has this star under close observation at Cuckfield since January has ascertained that a maximum of 2·9 m. occurred on February 11, which is fourteen days later than given by the table of sines in Prof. Schönfeld's second catalogue. The next minimum may be expected to fall about the middle of September, and the following maximum in the first days of July, 1886, assuming that there is a similar retardation to that assigned by the formula.

ASTRONOMICAL PHENOMENA FOR THE WEEK, 1885, MARCH 22-28

(For the reckoning of time the civil day, commencing at Greenwich mean midnight, counting the hours on to 24, is employed.)

At Greenwich on March 22

Sun rises, 6h. 0m.; souths, 12h. 6m. 53·8s.; sets, 18h. 13m.; decl. on meridian, 0° 49′ N.: Sidereal Time at noon, 6h. 16m.

Moon (at First Quarter on March 23) rises, 9h. 22m.; souths, 17h. 12m.; sets, 1h. 5m.*; decl. on meridian, 17° S.

Planet	Rises h. m.	Souths h. m.	Sets h. m.	Decl. at noon
Mercury ...	6 15 ...	12 40 ...	19 4 ...	4 ...
Venus ...	5 50 ...	11 28 ..	17 6 ..	4 ...
Mars ...	5 51 ...	11 38 ...	17 25 ...	3 ...
Jupiter ...	14 42 ...	21 57 ...	5 12* ..	13 ...
Saturn ...	9 3 ...	17 8 ...	1 13* ..	21 ...

...	9	...	Mercury at least distance from the Sun.

GEOGRAPHICAL NOTES

. R. VON LENDENFELD, in a letter to Prof. Cayley dated ry, January 24, 1885, writes as follows:—I have been sent : Geological Survey Department of this colony to make a ific investigation of the central part of the Australian Alps ave returned a few days ago. I found out that the peak, lered as the highest hitherto, which has been measured by d scientists and named Mount Kosciusko, is *not the highest*, nade the first ascent of the highest peak some distance r south. I calculated the height of the latter at 7256 feet ot Kosciusko has been measured at 7176, 7175, and, by f, at 7171 feet). I name this hill after our celebrated gist, the Rev. W. B. Clarke, Mount Clarke. Further, I ered indubitable signs of prehistoric glaciers above 5800 and photographed some beautiful *roches moutonnées*. A valley was filled at the glacial period by a glacier extending et up its sides. I had excellent weather, and photographed norama from the summit of Mount Kosciusko. I had one and a geological assistant with me. We camped only nights, and had glorious weather all the time. The upper of trees lies at a height of 5900 feet. Patches of snow are attached to the leeside of the main range above 6500 feet e year round—in the European Alps such little *névés* would e below 8000 feet—another proof for the lower tempera- nd greater amount of wet south of the equator, as our Alps -48° N., and Mount Kosciusko 37° S. I collected many s and geological specimens, and found the whole trip ly enjoyable and interesting. It froze every night, and I t tell you how happy and comfortable I felt in the brisk ir up there, after having been confined to the hothouse te of Sydney for a year.

E Vienna correspondent of the *Times* telegraphs that at a e meeting of the committee of the Imperial Geographical ty of Vienna, it has been resolved that Dr. Oscar Lenz, tary of the Society, should be sent on a new expedition to re the watershed between the Nile and the Congo. This ition has been planned chiefly by Baron Leopold Hofmann, Imperial Finance Minister, and now President of the ian African Association. Dr. Lenz will visit the stations International Belgian Society, and one of the objects of rney will be to find traces of Dr. Junker, Dr. Schnitzler rn in Egypt as Emin Bey), Signor Cassati, and Lupton Dr. Lenz's journey will be under the special patronage of rown Prince of Austria and the King of the Belgians, and st will be defrayed partly by the Geographical Society of a, partly by the Government and from private subscrip-

Dr. Lenz proposes to start early in May.

the meeting of the Geographical Society of Paris, held e 6th inst., M. Mascart in the chair, Prince Roland arte referred to the recent exploration of the Van Braam s in New Guinea.—A correspondent of the Society wrote Ciudad Bolivarin Venezuela that it was reported there that f the members of the Crévaux mission was still living in ity among a tribe of Indians, and it is also stated that ents of a paper were found in a Bolivian forest, on which written in letters of blood the name of the prisoner and e.—M. Teisserenc de Bort described the oasis of Djerid ois. It contains 9,700 inhabitants.—A communication was with reference to the tribes employed in the recent revolt in co, correcting the names given to them.—M. Schrader paper on the masses of snow moved about by the wind gat mountains. These masses are not carried about by e—they obey very simple laws, which cause them to be ited at spots where the wind is diminished in intensity, ive them forms which may easily be analysed when we take count the quality of the snow, the force and direction of find, and the contour of the mountains.—M. Rabot de- d the results of the mission with which he was charged by inister of Public Instruction to explore Northern Finland ussian Lapland. He explored especially the valleys of the r and Talom, as well as Lake Enara. The whole region is one immense forest, with lakes and peat-bogs scattered every- where, and cut up by numerous water-courses. These rivers are the only means of communication, but their navigation is most difficult, on account of cascades and rapids. Lake Enara, which is drained by the Paswig, is described by M. Rabot as a veritable inland sea, with hundreds of islets covered with mag- nificent pine trees. The climate is very rigorous. Winter begins in September, and the ice is still in the ground in the beginning of June. The spring is short, but comparatively warm, and it is not rare to see the frost again in August. The country around Lake Enara is level and little broken, and forms a depression between the plateau of Finmark and the masses of hills which stud Russian Lapland.

A WORK which will shortly be published by Prince Roland Bonaparte deals with the populations of Dutch Guiana from an anthropological and sociological point of view. He has studied three groups of the population: (1) the Indians (Caribs); (2) wild Negroes, or Negroes of the woods, being fugitive slaves who have returned to savage life; (3) freed slaves or settled Negroes. The section on the Negroes who have returned to their original state is probably the most interesting of the three. Many of these are descendants of slaves who fled from ill-treat- ment in the early days of the colony to the woods and inaccessi- ible solitudes of the highlands. In 1712, when Admiral Cassard laid siege to Paramaribo, the planters sent away their slaves into the interior, so that they should not fall into the invader's hands, and they refused to return after the peace. Gradually their number augmented, and these Negroes formed themselves into villages and cultivated land. They grew so powerful that after several bloody and expensive wars, the Colonial Govern- ment found it expedient to make a treaty of peace, recognising them as allies, in 1762. At the present moment they number 8000 souls, and are divided into four sections or tribes, according to the locality in which they have settled. They appear to have preserved most of the characteristics of the Negro, but they have adopted many of the habits and modes of life of the Indians, by whom they are surrounded.

THE first number of the *Scottish Geographical Magazine*, the organ of the new Scottish Geographical Society, has been issued. It aims at being much more than the organ of the Society, how- ever. It begins with Mr. Stanley's opening address, and a some- what perfervid article on Scotland and geographical work. This is followed by a most instructive article by Prof. James Geikie on the physical features of Scotland, accompanied by a map essentially new in design and nomenclature. The geographical notes occupy about fourteen pages, and are unusually full and comprehensive, aiming at a nearly exhaustive chronicle of geo- graphical progress in all departments. This is followed by a *résumé* of geographical literature for 1884, new books and new maps. Besides Prof. Geikie's map there is one of the river basins of Africa, and a portrait of Mr. Stanley. Altogether the *Magazine* is a valuable addition to the literature of its class, creditable to the enterprise of the Society and the knowledge and intelligence of its editors.

ACCIDENTAL EXPLOSIONS PRODUCED BY NON-EXPLOSIVE LIQUIDS[1]

TEN years ago the lecturer discussed in some detail the various causes of the continually recurring casualties which are classed under the head of accidental explosions, and he then had occasion to compare the causes of coal-gas explosions, the occurrence of which is as deplorably frequent now as it was then, with those of accidents connected with the transport, storage, and use of volatile inflammable liquids which are receiving extensive application, chiefly as solvents and as illuminating agents.

Within the last few years he has had occasion to devote special attention to the investigation of instances of this class of accident, and to examine more particularly into the probable causes of frequent casualties connected with the employment of lamps in which the various products included under the general designations of petroleum and paraffin oil are burned. The latter branch of these inquiries, which is still in progress, has been conducted in association with Mr. Boverton Redwood, the talented Secretary and Chemist of the Petroleum Association, and with the valuable aid of Dr. W. Kellner, Assistant-Chemist

[1] Address delivered at the Royal Institution of Great Britain, Friday, March 13, 1885, by Sir Frederick Abel, C.B., D.C.L., F.R.S., M.R.I.

of the War Department. Although it may be hoped that their continuation will lead to further data and conclusions of practical and public importance, it is thought that some account of facts already elicited may interest the members of the Royal Institution, and possess some general value.

Ever since liquids which, more or less rapidly, involve inflammable vapour when freely exposed to air, or partially confined, have been in extensive use, casualties have occurred from time to time through the accidental or thoughtless ignition of the mixtures of vapour and air thus formed, whereby more or less violent and destructive explosions have been produced, often followed by the ignition of the exposed liquid which is the source of the explosive mixture, and by the consequent frequent development of disastrous conflagrations.

Many instances are on record of explosions, sufficiently violent to produce effects destructive or injurious to life and property, resulting from the application of flame to vessels which had contained either the more volatile coal-tar or petroleum-products, or strong spirituous liquids, and which, though they had been entirely or nearly emptied of their contents, still contained, or retained by absorption within their body, some of the volatile liquid, this having, by evaporation into the air in the emptied receptacle, produced with it a more or less violently explosive mixture. Thus, a loud explosion occurred at the entrance of a lamp-maker's shop in Whitecross Street, which was found to have been caused by a boy throwing a piece of lighted paper into a cask standing under the gateway, which had contained benzoline; two boys were very seriously injured by the blast of flame which was projected from the barrel. A perfectly analogous accident was soon afterwards reported in the papers as having occurred at Sheffield, with serious injury to the author of the catastrophe and another boy; and a very similar case occurred at Exeter during the removal of some empty benzoline barrels, consequent upon a boy applying a lighted match to the hole of one of them. Again, at Spaxton in Somersetshire, a young man applied a light to the hole of a benzoline cask, described as nearly empty, which was standing in the road, when three young men were blown across the road, one of them being so seriously injured about the head that he died.

Explosions with similarly disastrous results have also been publicly recorded as having resulted from the application of a light to rum puncheons and whisky casks, even some time after they have been emptied of their contents, the evaporation of the alcohol absorbed by the wood having sufficed to convert the confined air into a violent explosive mixture.

The readiness or extent to which inflammable vapour is evolved from those products of the distillation of petroleum, or of shale or coal, which are used for illuminating purposes, differs of course considerably with the character of these liquids. Those which are classed as petroleum spirit (known as gasoline, benzine, benzoline, naphtha, japanners' spirit, &c.), and in regard to which there exist very special precautionary enactments, are, it need scarcely be said, of far more dangerous character than those classed as burning oils, which include the paraffin oils obtained from shale and the so-called flashing points of which range from 73° to above 140° Fahrenheit. The rapidity with which the vapours, evolved by the more volatile products on exposure to air, or by their leakage from casks or barrels, diffuse themselves through the air, producing with it more or less violent explosive mixtures, has been a fruitful source of disaster, sometimes of great magnitude. The lecturer had occasion to refer, in his discourse of 1875, to an accident at the Royal College of Chemistry of which he was a witness, in 1847, when the lamented Mr. C. B. Mansfield was engaged in the conversion of a quantity of benzol into nitrobenzol in a capacious glass vessel, which suddenly cracked, allowing the warm liquid hydrocarbon to escape and flow over a large surface. This occurred in an apartment 38 feet long, about 30 feet wide, and 10 feet high; there was a gas jet burning at the extremity of the room opposite to that where the heated liquid was spilled, and within a very brief space of time after the vessel broke, a sheet of flame flashed from the gas jet along the upper part of the room, to the spot where the fluid lay scattered.

The origin of a fire which occurred at some mineral oil stores at Exeter in 1882 affords another striking illustration of the great rapidity with which the vapour of petroleum spirit will diffuse itself through the air. The store which caught fire, and which contained both petroleum oil and spirit, or benzoline, was one of a range of arched caves upon the bank of a canal, being separated from it by a roadway about 30 feet wide. It was a standing rule at the stores that no light should be taken into one containing benzoline. The casks which contained the liquid were to be removed, and the foreman, desirous of beginning this work early, and forgetful of the rule, went to the store shortly before daylight, carrying a lighted lantern, which he placed upon the ground at a distance of several feet from the door. He then proceeded to open these. As he did so he noticed a very powerful odour of benzoline, and, almost immediately, he saw a flash of flame proceed from the lantern to the store. He had just turned to escape, when an explosion occurred which blew the doors and the lantern across the canal; the benzoline in the store was at once inflamed, and flowed out into the road and upon the surface of the water, lying a small vessel which lay against the quay, and setting fire to the stores of benzoline contained in two neighbouring caves.

Many exemplifications might be cited of the dangers arising from the accidental spilling or escape of petroleum spirit or even of oils of very low flashing point) in the ordinary course of dealing with these liquids, as in stores where there is but imperfect ventilation, and in some part of which a flame exists, or is carelessly introduced; or from the escape of spirit or its vapour from stores or receptacles to adjacent spaces where its existence being unsuspected, the ignition of the resulting explosive mixture of vapour and air may be at any time brought about.

Without referring to accidents which have been due to flagrant carelessness in introducing a flame or striking a light in a place where petroleum vapour is likely to exist in the air, or where some form of spirit has been accidentally spilled, a few instances may be quoted which illustrate the magnitude of casualties liable to arise from the causes just referred to. Some years ago an explosion productive of much damage occurred in a street at Greenwich, and was clearly traced to the entrance into the sewer of some petroleum products (from a neighbouring patent gas factory); the vapours from these had diffused themselves through the air in the sewer to a considerable distance, forming with it an explosive mixture which must have been accidentally ignited at one of the sewer openings in the street above. Last year a similar accident occurred at Newport in Monmouthshire, a quantity of benzoline having escaped into a sewer from a neighbouring store; the ignition of the resulting explosive mixture of vapour and air, with which a considerable length of the sewer became filled, tore up the roadway to some distance, several persons being thrown down. A terrific disaster of the same class was reported from San Francisco in November, 1880. During the driving of a tunnel in the San Jose-Santa Cruz Railway, a vein of petroleum became exposed by the excavators, who were, of course, working with naked lights. Three such explosions occurred in consequence, in rapid succession, resulting in the death of twenty-five Chinamen and in the injury of seventeen others and two white men.

Another accident, which occurred near Coventry nearly [illegible] years ago, may be quoted in illustration of the [illegible] manner in which explosive gas-mixtures may exist in localities which, to the superficial observer, may appear to have no connection with a neighbouring locality where volatile liquids are liable to escape confinement.

A dealer in benzoline spirit kept his small stores of [illegible] (from 20 to 80 gallons) in an apartment of his house, [illegible] basement, the floor of the room being paved with [illegible] At a distance of about three feet from the stone-room there was a well, the depth of which to the surface of the water was [illegible] feet. The well was closed in almost entirely with planks [illegible] with earth. The water in the well being found [illegible] had the latter uncovered, with a view to its being cleared [illegible] The workman in charge of the operation, after having [illegible] engaged for three hours in pumping out a large quantity of [illegible] water, lowered a lighted candle into the well, according to [illegible] usual practice, to see whether he could descend with safety, when, while bending over the opening, he perceived a [illegible] flame shooting upwards, and was violently thrown back [illegible] badly burnt, a woman who was watching him being [illegible] injured. The benzoline which had been spilled from time to time in small quantities in filling the cans of customers had readily passed through the porous brick upon which it fell, and gradually permeating the soil beneath, had, in course of time, drained into the adjacent well. That this most [illegible] circumstances described would have been self-evident to [illegible] acquainted with the behaviour of these liquids and with

nt circumstances. In localities where large quantities
r some time been stored in the usual casks or barrels,
no difficulty in "striking oil" by sinking a well in the
iately adjacent ground, in consequence of the large
of leakage of the spirit or oil which must unavoidably

Even in the absence of leakage from the openings of
rrels, or from any accidental imperfection, considerable
n of the volatile liquid, and consequent escape by evapor-
hrough the wood itself, must occur in large petroleum-
especially if much exposed to the sun, and in the holds
s where the temperature is generally more or less high.
he precaution adopted of rinsing the barrels before use
stiff solution of glue is not effectual in preventing the
of the spirit from these causes, as the effect of alterna-
f temperature upon the barrels must tend to reopen any
d places temporarily closed by the glue. Even at very
ve depôts, where special arrangements were adopted to
n the stores uniformly at a very moderate average tem-
e, the loss of petroleum spirit from leakage and evapora-
s estimated, ten years ago, to amount to about 18 per
f the total stored, while the average loss from the same
upon petroleum oil was about 9 per cent. By the intro-
, from time to time, of improvements of the arrange-
the loss of spirit by leakage and evaporation has been
nsiderably reduced, amounting to less than 8 per cent. in
nstructed stores, while at some petroleum stores, more
lly in Germany, the loss of oil from leakage is now said
exceed 1 per cent.

n the case of the loss of coal-laden ships by explosions on
h seas, such loss has probably, in many cases, been due
levelopment of gas from the cargo, and to its diffusion
air of parts of the ship more or less distant from the
roducing an explosive atmosphere which might become
by the conveyance or existence of a light or fire, where
ence was not deemed dangerous; so also it is not im-
le that the supposed loss by effects of weather of missing
m-laden vessels may have occasionally arisen from fire,
in the first instance by the diffusion of vapour escaping
e cargo through the air in contiguous parts of the ship,
accidental ignition of the explosive atmosphere thus
ed.

ossibility of such disasters has been demonstrated by the
t occurrence of accidents of this class in ports or their

A very alarming instance of the kind occurred in 1871
Thames off Erith. Two brigantines had nearly com-
the discharge of their cargoes of petroleum spirit
lba", when another vessel, the *Faith*, from Nova
containing upwards of 2000 barrels of the same material,
with other inflammable cargo, anchored alongside
This ship had encountered very severe weather, and it
en necessary to batten down the hatches; the cargo in
d had consequently become enveloped in the vapour
had escaped from the casks. On the removal of the
, an explosive mixture was speedily produced by access
and, through some unexplained cause, became ignited
after the vessel anchored. A violent explosion followed,
e vessel was almost instantly in flames, the fire being
communicated to the other two ships, which were with
y saved, after sustaining considerable injury, while the
n which the fire raged uncontrollably, was after a time
to a spot where she could burn herself out and sink
damage to the other shipping. Three of the crew were
y injured by the explosion, and the mate was blown to
sistance into the water.

ne, 1873, a vessel (the *Maria Lee*), laden with 300 barrels
oleum and other inflammable cargo, was destroyed by
the Thames near the Purfleet powder magazines, im-
upon the explosion in her of a mixture of petroleum-
and air; and a similar accident occurred about the same
Glasgow harbour. In the case of the *Maria Lee* it was
proved that the vapour resulting from leakage and evapo-
f the spirit in the hold had diffused itself through the
ing the night, which was very hot, the hatches having
pt closed and covered with tarpaulin, in consequence of
urrence of a thunderstorm. Upon the captain entering
n in the after part of the ship early in the morning (and
y striking a light) a loud explosion took place, and flame
diately seen issuing from the fore-part of the ship.
r similar casualty to the foregoing occurred at Liver-
r years afterwards, in a small vessel laden with petroleum-
spirit, which proved not to have been at all adapted by internal construction for the safe carriage of such a freight. The cargo of 214 barrels of spirit had been stowed on board, and the hatches were put down and covered with tarpaulin. The cabin and forecastle of the smack were below deck, and were only separated by a thin partition from the hold. The loading had been completed between six and seven o'clock in the evening, and at about eight o'clock the captain went into the cabin and kindled a lamp. A man upon deck, who with another was injured by the explosion and fire, saw the light burning in the forecastle, and almost immediately afterwards the deck was lifted and the man was thrown some distance, while flame issued from the hold. The captain was terribly burned, and died shortly afterwards. In vessels which are constructed for the American petroleum trade, the cabins and forecastles are all upon deck, that part of the vessel which carries the freight, between decks, being as completely as possible separated from the other parts of the ship.

In some instances, ships laden with petroleum oil have become inflamed, in an unexplained manner, without the occurrence of any noticeable explosion, as was the case last year with a large vessel (the *Aurora*) in the port of Calcutta, after she had discharged more than half her cargo of 59,000 cases. The vessel burned for nine hours, the river becoming covered with burning oil as she gradually filled with water; the direction of the wind and the condition of the tide at the time of her sinking fortunately prevented the fire from reaching the shipping higher up the river.

There is no doubt that, while with cargoes of the more volatile petroleum products, classed as spirit, the greatest precautions are necessary to guard against the possible ignition of more or less explosive mixtures of vapour and air which will be formed in the stowage spaces of ships, and which may extend to other parts of the vessels unless very efficient ventilation be maintained, ships laden with the oils produced for use in ordinary petroleum or paraffin lamps, and which, yielding vapours at temperatures above the standard fixed as a guarantee of safety, incur comparatively very little risk of accident, provided simple precautions be observed. If, moreover, by some act of carelessness, or some accident not guarded against by the prescribed precautions, a part of such cargo does become ignited, the prompt and, as far as practicable, complete exclusion of air from the seat of fire, by the secure battening down of the hatches, will most probably save the ship from destruction. There are numerous records of vessels having discharged cargoes of petroleum oil, many barrels of which have been found greatly charred on the outside, occasionally even to such an extent that the receptacle has scarcely sufficient strength remaining to retain its contents. A remarkable illustration of the controllable nature of a fire in a petroleum-laden ship was furnished by the ship *Joseph Fish*, laden with refined petroleum, lubricating oil, and turpentine, which, a fortnight after leaving New York (in September, 1870), was struck by lightning during a heavy squall, the hatches being closed at the time. Smoke at once issued from below, and the force-pumps were set to work directly to keep the fire down. The hatches were removed for examination as the fire appeared to gain ground, but were immediately replaced, and, after further pumping, as the fire appeared to increase, and an explosion was feared, the crew took to their boats, remaining near the ship. Eight hours afterwards they were picked up by a passing ship, which remained near the *Joseph Fish* until daylight. Her captain then returned on board, and as he found that the fire appeared to be out, the crew returned and the ship resumed her voyage, reaching the port of London without further incident, except that, during the use of the pumps for removing the water, considerable quantities of petroleum and turpentine were pumped up with it from the hold. When the cargo was discharged, a large number of the barrels bore evidence of the great heat to which they had been exposed; several casks had gone to pieces, and the staves of others were charred quite half-way through, although they still retained their contents.

The lecturer had occasion, ten years ago, to dwell upon the recklessness with which fearful risks were incurred, in some cases no doubt ignorantly, but in others scarcely without a knowledge, on the part of those who were responsible, of the nature of the materials dealt with, by transporting volatile and highly inflammable liquids together with explosive substances in barges or other craft, and in doing so, moreover, without the adoption of even the most obvious precautions for guarding against access

of fire to the contents of those vessels. The instance of the explosion, in 1864, of the *Lottie Sleigh* at Liverpool, laden with 11½ tons of gunpowder, in consequence of the accidental spilling and ignition of some paraffin oil in the cabin of the ship, illustrated the danger incurred in permitting these materials to be together on board a vessel, and should have furnished some warning by the publicity it received; but the explosion, ten years later, on the Regent's Park canal, of the barge *Tilbury*, revealed the continued prevalence of the same reckless disregard of all dictates of common prudence in dealing with the joint transport of explosives and volatile inflammable liquids.

The efficient laws and Government inspection to which all traffic in explosives has since then been subject, have rendered the recurrence of that identical kind of catastrophe almost out of the question, but an illustration has not been wanting quite recently of the fact that, but for the respect commanded by the rigour of the law, barges passing through towns would probably still carry freights composed of petroleum spirit and powder or other explosives, being at the same time provided with a stove, lamp, and matches for the convenient production of explosions. In August, 1883, an explosion occurred on the canal at Bath, in a barge which sank immediately, the master being slightly injured; the freight of the vessel consisted of petroleum, benzoline, and lucifer-matches.

The last four years have furnished several very remarkable illustrations of great injuries inflicted on ships by explosions, the origin of which was traced to the existence on board of only small quantities of some preparation containing petroleum spirit, or benzoline, with the nature of which the men who had charge of them were not properly acquainted. These materials had, consequently, been so dealt with as to become the means of filling more or less confined spaces in the ships with an explosive atmosphere which, when some portion of it reached a flame, was fired throughout, with violently destructive effects.

The first authenticated case of an accident due to this cause occurred in June, 1880, on board the Pacific Steam Navigation Company's steamer *Coquimbo*, shortly after her arrival in the morning at Valparaiso from Coquimbo. A violent explosion took place, without any warning or apparent cause, in the fore-peak of the vessel, blowing out several plates of the bow and doing other structural damage, besides killing the ship's carpenter; the explosion could only be accounted for by the circumstance that a small quantity of a benzoline preparation used for painting purposes (probably as "driers") was stored in the fore-peak and that a mixture of the vapour from this with the air had become ignited. The sufferer was the only person who could have thrown light upon the precise cause of the accident, but there was no other material whatever in that part of the ship to which the explosion could have been in any way ascribed.

In May, 1881, an explosion of a trifling character occurred on board H.M.S. *Cockatrice* in Sheerness Dockyard, in consequence of a man going into the store-room with a naked light and holding it close to a small can which was uncorked at the time, and which contained a preparation recently introduced into the naval service as a "driers" for use with paint, under the name of *Xerotine Siccative*. This preparation, which was of foreign origin, appears to have been adopted for use in the naval service and to have been issued to H.M.'s ships generally without any knowledge of its composition and without attention being directed to the fact that it consisted very largely of the most volatile petroleum spirit, which would evaporate freely if the liquid were exposed to air at ordinary temperatures, and the escape of which from a can, jar, or cask, placed in some confined and non-ventilated space, must speedily diffuse itself through the air, and render the latter more or less violently explosive.

When attention was directed to the highly inflammable character of this xerotine siccative by the slight accident referred to, official instructions were issued by the Admiralty, in June, 1881, to ships and dockyards that the preparation should be stored and treated with the same precautions as turpentine and other highly inflammable liquids or preparations.

The following November, however, telegraphic news was received of a very serious explosion on board H.M.S. *Triumph*, then stationed at Coquimbo, due to the xerotine siccative. The explosion took place early in the evening of November 23, and originated in one of the paint-rooms of the ship; the painter, and a marine who was assisting him, were in the upper paint-room at the time; the former received severe internal injuries and afterwards died, the latter was killed at once. The ... standing at the open door of the sick bay further from ... plosion was instantaneously killed, others in close ... receiving only superficial injuries. Altogether there were killed, two dangerously wounded—of whom one died—injured by the explosion.

The results of the official inquiry held at Callao ... conclusion that the explosion was caused by the ignition ... explosive gas-mixture produced by xerotine siccative ... leaked from a tin kept in a compartment under the ... and quite at the bottom of the ship, usually termed ... hole;" that locality having been considered by the ... the ship as the safest place in which to keep this material ... dangerous nature of which his attention had been recently ... by the receipt of the Admiralty Circular. It transpired ... painter had sent his assistant down to this compartment ... the paint-room to fetch some paint. The man, who had ... lantern with him, while opening the hatch, which had ... been opened for three days, made a remark that there ... horrible smell; the chief painter told him to return, as ... the smell was due to foul air, and immediately afterwards ... explosion occurred.

The tin can which had contained six gallons of the ... found, after the accident, to have received injury as if ... heavy body had fallen, or been placed, upon it; this ... to have been done before the explosion, and there ... that the liquid had leaked out of the can, and had ... into the air in the compartment beneath the paint-room ... probably also to some extent in the adjoining ... damage done was very considerable. An iron ... from one paint-room to the other was so twisted ... lost all semblance of originality, the wooden bulkhead ... the upper paint-room and sick bay was completely blown ... the framing of the ship's side in the sick bay was blown ... and broken, the furniture in the latter was completely ... and the bedding and clothes of the men near the explosion ... much burned. The inquiries which followed upon the ... able accident showed that, while due precautions were ... store the supplies of mineral oil used for burning ... turpentine and of spirit, which were sent to different ... stations for supply to the fleet, in special parts of the ... deck, this highly inflammable liquid, which was ... dangerous than other stores of this class, had been ... freight-ships as common cargo, being stored in the hold ... any precautions. A stone jar which was advised as ... a supply had arrived at its destination in the ... empty, the contents having leaked out and evaporated ... passage out, so that the vessel carrying it had been ... exposed to very great danger.

(*To be continued.*)

PROGRAMME OF WORK TO BE ... AT THE U.S. NAVAL OBSERVATORY, WASHINGTON, D.C., DURING THE ... BEGINNING JANUARY 1, 1885[1]

The Great Equatorial

1. OBSERVATIONS of a selected list of double ... be continued. These stars are such as have rapid motions, or which present some other interesting peculiarities.

2. Conjunctions of the inner satellites of Saturn ... opposition of the planet will be observed. There will be made a complete micrometrical measurement of the ... of the ring.

3. There will be made three drawings of Saturn ... opposition; one at or near opposition; and one after ...

4. The observations which have been begun for ... and for the temperature coefficient of the screw of the micrometer, will be finished.

The Transit Circle

1. Observations of the sun will be made whenever ... sary ephemeris stars can be observed, and the requisite instrumental corrections determined.

2. The moon will be observed through the whole ...

3. The major planets will be observed from ... times, near opposition.

[1] Transmitted by Commodore S. R. Franklin, U.S.N. ...

ach minor planet will be observed at least five times, near ion, when practicable.
bservations of the list of miscellaneous stars will be l as soon as practicable.

THE TRANSIT INSTRUMENT

bservations will be made as often as practicable for time, correction of the standard meantime clock; and compa- will be made daily for such correction.
bservations for the right ascensions of the sun, moon, and lanets to be made as frequently as possible; observations major planets, and of the brighter of the minor planets, to e near opposition.
he observations made during 1883 will be prepared for tion; and the computations of those of 1884 continued.

THE 9·6-INCH EQUATORIAL

rvations will be made:—
f all the minor planets whose brightness at opposition is than their mean brightness.
f comets, to determine position and physical peculiarities.
f occultations of stars by the moon.
hen arrangements shall have been made to photograph , any sun-spots which show any decided peculiarities in otographs will be examined with the spectroscope.

THE PRIME VERTICAL TRANSIT INSTRUMENT

rvations of a selected list of stars in conjunction with the Observatory at Lisbon, in pursuance of the plan recom- l by the International Geodetic Association, for the deter- n of variability of latitude.

TIME-SERVICE AND CHRONOMETERS

time-balls at Washington and New York will be dropped noon of the 75th meridian; and the noon signals will nded to such other places throughout the country as may rable, as rapidly as arrangements may be made.
rating of chronometers will be continued as heretofore.
orological observations will be made as usual.

THE MURAL CIRCLE

rvations will be made of stars down to the 7th magnitude f ten degrees North declination, the positions of which ot been recently determined at some northern observa- he observing list to be formed of all stars from Gould's metria Argentina visible here, and not found in Yarnall's gue, the Transit Circle list of B.A.C. stars, or the recent gue of the Glasgow Observatory.

SOCIETIES AND ACADEMIES

LONDON

Royal Society, March 5.—"On the Atomic Weight of Glucinum (Beryllium)." Second Paper. By T. S. Humpidge, Ph.D., B.Sc., Professor of Chemistry in the University College of Wales, Aberystwyth. Communicated by Prof. E. Frankland, F.R.S.

This paper is a continuation of one previously communicated to the Royal Society (*Proc. Roy. Soc.*, vol. xxxv. p. 137). The author has prepared a sample of metallic glucinum, having the composition—

Gl	...	...	...	99·20
GlO	...	...	...	0·70
Fe	...	...	...	0·20
				100·00

and has determined its specific heat at varying temperatures up to 450° with the following results (for pure glucinum):—

$c_{14°}$	0·4286
$c_{212°}$	0·4515
$c_{311°}$	0·4699
$c_{350°}$	0·4885
$c_{374°}$	0·5105
$c_{412°}$	0·5199
$c_{442°}$	0·5403

These results correspond to the following empirical formula for the true specific heat of the metal at varying temperatures—

$$k_t = k_0 + 2at + 3bt^2,$$

or with numerical values—

$$k_t = 0{\cdot}3756 + 0{\cdot}001062t - 0{\cdot}000001142t^2,$$

whence the following values for k_t are calculated:—

k_0	0·3756
k_{100}	0·4702
k_{200}	0·5420
k_{300}	0·5910
k_{400}	0·6172
k_{500}	0·6206

If these values are graphically represented the curve so obtained reaches a maximum at about 470°, and then falls; but whether it represents the specific heat at higher temperatures than 500° is doubtful. The specific heat of glucinum then rises rapidly up to about 400°, and remains approximately constant between 400° and 500° at 0·62. If this number is multiplied by 9·1 it gives the atomic heat 5·64. Glucinum, therefore, belongs to the same class as carbon, boron, and silicon, which agree with Dulong and Petit's rule at high temperatures only. And the true atomic weight is that required by the periodic law—viz. 9·1 and not 13·6, as was previously deduced from the specific heat between 10° and 100°.

This conclusion is confirmed by the author's determinations of the vapour-densities of glucinum chloride and bromide in a platinum vessel. The experiments were done in an atmosphere of carbonic acid collected over mercury after Meier and Crafts (*Berlin. Ber.*, xiii. 851), and gave the following results:—

I. *Glucinum Chloride*

	Substance	Displaced CO_2	t	d
Experiment i.	26·4 mgrms.	7·47 c.c.	635°	2·733
,, ii.	28·0 ,,	7·98 ,,	785°	2·714

The theoretical density of $Gl'Cl_2$ is 2·76, and this formula, therefore, represents the molecule of this compound.

II. *Glucinum Bromide*

	Substance	Displaced CO_2	t	d
Experiment ii.	35·9 mgrms.	4·28 c.c.	608°	6·487
,, iii.	61·4 ,,	7·53 ,,	630°	6·276
,, iv.	26·0 ,,	3·22 ,,	606°	6·245

The density of $Gl'Br_2$ is 5·84, and that of $Gl''Br_2$ is 8·76. The agreement in this case is not so close as in the case of the chloride, but is sufficiently near to show that the true molecular formula is $Gl'Br_2$, and not $Gl''Br_2$. Thus, the vapour-density of both compounds necessitates the atomic weight 9·1. The result is a striking argument in favour of the value of deductions drawn from the periodic law in regard to the atomic weight of an element, and shows that such deductions will in future form one of the most important factors in fixing a doubtful atomic weight. The author did not appreciate the full value of the periodic law when he wrote his former paper, otherwise he would probably have stated his conclusions less positively.

Zoological Society, March 3.—Prof. W. H. Flower, F.R.S., President, in the chair.—Dr. E. Hamilton made some remarks on the supposed existence of the Wild Cat (*Felis catus*) in Ireland, as stated at a former meeting, observing that there was no record of the Wild Cat being indigenous to that country. Dr. Hamilton believed that the cat shown at the meeting in question was only the offspring of domestic cats born and bred in the woods of that district.—A letter was read from Mr. J. H. Thomson, C.M.Z.S., giving the locality of *Helix* (*Hemitrochus*) *filicaste*, which had been previously unknown.—Dr. A. Günther, F.R.S., exhibited and made remarks on the skin of a singular variety of the Leopard which had been obtained in South Africa. The back in this specimen was black, and the tail reddish gray, while the usual characteristic spots of the ordinary leopard were nearly altogether absent.—Mr. H. H. Johnston, F.Z.S., gave a general account of the principal animals observed by him during his recent journey to Kilimanjaro and his stay on that mountain.—Mr. Oldfield Thomas read a report on the Mammals obtained and observed by Mr. Johnston during his expedition.—Capt. G. E. Shelley read a report on the birds collected by Mr. H. H. Johnston in the Kilimanjaro district. The collection contained examples of fifty species, six of which were believed to be new to science.—Mr. Charles O. Waterhouse read a paper on the insects collected on Kilimanjaro by Mr. H. H. Johnston, and gave the descriptions of six new species of Coleoptera, of which examples occurred in the collection.—Prof. F. Jeffrey Bell read a description of a Nematoid Worm (*Gordius vermicosus*) obtained by Mr. Johnston on Kilimanjaro, which was found to be parasitic on a species of *Mantis*.—Mr. E. J. Miers communicated the description of a new variety of River-Crab of the genus *Thelphusa* (*T. depressa*, Krauss, var. *Johnstoni*), which had been obtained by Mr. H. H. Johnston in the streams of Kilimanjaro.—Mr. Francis Day read the fourth of the series of his papers on races and hybrids among the Salmonidæ, containing the account of the Howletown experiments from November, 1884, to the present time.—Prof. Ray Lankester read some notes on the heart described by Sir Richard Owen in 1841 as that of *Apteryx*, and came to the conclusion that the heart in question was that of an *Ornithorhynchus*.

Chemical Society, February 19.—Dr. W. H. Perkin, F.R.S., President, in the chair.—The President announced that Mr. Warren de la Rue, F.R.S., had presented a bust of the late Prof. Dumas. The following papers were read:—On benzoylacetic acid and some of its derivatives, part 2, by Dr. W. H. Perkin, jun.—On roughened filter-paper, by E. E. H. Francis.—The detection and estimation of iodine, by Ernest H. Cook, B.Sc. (Lond.).—Note on methylene chlor-iodide, by Prof. J. Sakurai.—A quick method for the estimation of phosphoric acid in fertilisers, by J. S. Wells, Columbia College.—On the luminosity of methane, by Lewis T. Wright, Assoc.M.Inst.C.E.—On the oxides of nitrogen, by Prof. W. Ramsay and J. Tudor Cundall. In this research it is shown—(1) That the green or blue liquid obtained by the action of arsenious anhydride on nitric acid consists of a mixture of nitrous anhydride and nitric peroxide, in proportions depending on the strength of the nitric acid and the temperature at which the volatile liquid is condensed. (2) That if a dehydrating agent, such as sulphuric acid, be present in sufficient quantity the distillate consists of pure peroxide, and that this process is by far the most convenient one for the preparation of the peroxide. (3) That if oxygen be passed over the blue liquid, the vapours condensed in a freezing mixture are still blue or green; a great excess of oxygen is necessary to effect conversion from nitrous anhydride into peroxide. (4) That when excess of nitric oxide is passed along with the peroxide into a cooled bulb, the trioxide is produced, the amount of nitric oxide depending on the temperature of the condenser. (5) Vapour-density of a liquid of a deep blue colour, containing about 30 per cent. of trioxide and 70 per cent. of peroxide, shows that the trioxide cannot exist in the gaseous state, but at once dissociates into nitric oxide and peroxide on changing to gas. The theoretical vapour-density of such a mixture was calculated from a formula deduced from the second law of thermodynamics by J. Willard Gibbs, which shows the relations between temperature, pressure, and vapour-density of the mixture of NO_2 and N_2O_4 in the gaseous peroxide; and it was found that the vapour-densities of a mixture of $(NO_2 + N_2O_4)$ (partly present in the original liquid as peroxide, partly formed by the decomposition of the N_2O_3 present into NO and $(NO_2 + N_2O_4)$) with the NO produced by the decomposition of the N_2O_3, calculated by means of Gibbs' formula, are identical, within limits of experimental error, with those obtained by direct experiment. (6) That presence or absence of moisture does not appear to affect the reaction between NO and O_2. (7) It is probable that N_2O_3 undergoes dissociation with rise of temperature, even when liquid.—Discussion:—Dr. Armstrong said that he had listened to the paper with great interest, as he had made numerous experiments on the subject, and had long been of opinion that N_2O_3 did not exist, at all events as gas. The authors' observations, whereby they were led to this conclusion, were of considerable importance, and it was to be hoped that are long confirmatory evidence that would more directly appeal to chemists would be forthcoming. It was noteworthy that there was no recorded evidence proving the existence of N_2O_3 as gas. Gay-Lussac's experiments, published in 1816, showed that nitric oxide and oxygen only reacted in the proportions to form N_2O_4, and that reactions in proportions corresponding with the production of N_2O_3 only took place in presence of alkali. The method adopted by the authors did not suffice to prove the existence of N_2O_3, even as liquid, and the results could be equally well interpreted on the assumption that they were dealing with a solution of NO in N_2O_4. It was to be expected that N_2O_4 would be a good solvent of NO, as it appeared to be the case that bodies which are related are easily miscible, phosphorus, for example, being very soluble in PCl_3, and sulphur in CS_2 and S_2Cl_2. One observation made by the authors did, however, support their view, viz. the observation that the blue liquid was with great difficulty oxidised by passing oxygen into it. In all his experiments, Dr. Armstrong had found that the reactions attributed to N_2O_3 could be equally well explained by the presence of N_2O_4 and NO. As to the action of arsenious oxide on nitric acid, in his opinion, *nitrous acid* was *the* product, and the manner in which this underwent change entirely depended on the conditions. In dilute solution, NO would be produced in accordance with the equation: $3HNO_2 = 2NO + HNO_3 + H_2O$; but in presence of nitric acid the reaction $HNO_2 + HNO_3 = N_2O_4 + H_2O$ would take place, and would more and more preponderate the less the amount of water present. The addition of sulphuric acid would of necessity favour the latter mode of change. When N_2O_3 is passed into sulphuric acid, nitrosyl-sulphate and nitric acid are formed; in presence of NO the latter is reduced to nitrous acid which also forms nitrosyl-sulphate with the sulphuric acid, so that a mixture of NO and N_2O_3 in proper proportions precisely acts as though it were N_2O_3.

Anthropological Institute, March 10.—Francis Galton, F.R.S., President, in the chair.—The election of G. F. Laidlay was announced.—Mr. James G. Frazer read a paper on certain burial customs as illustrative of the primitive theory of the soul. The Romans had a custom that when a man who had been buried reported to have died abroad returned home alive, he should not enter his house, not by the door, but over the roof. This custom (which is still observed in Persia) owed its origin to certain primitive beliefs and customs with regard to the dead. The ghost of an unburied man was supposed to haunt and trouble the

especially his relatives. Hence the importance attached burial of the dead; and various precautions were taken e ghost should not return. When the body of a dead ald not be found, he was buried in effigy, and this fictitious was held to be sufficient to lay the wandering ghost, for it nciple of primitive thought that what is done to the effigy n is done to the man himself.—The director read a paper nirel F. S. Tremlett, on the sculptured dolmens of the an. About eighty sculptures had been found, invariably interior surfaces of the cap-stones and their supports. It rkable that they are confined within a distance of about miles, and are all situated near the sea-coast, beyond although the megaliths are numerous, there is a complete e of sculptures. The sculptures vary in intricacy from wave-lines and cup-markings to some that have been ed to the tattooing of the New Zealanders.

logical Society, February 25.—Prof. T. G. Bonney, President, in the chair.—Bennett Hooper Brough, Nath Datta, Robert Stansfield Herries, William Herries, Rev. Edward Jordon, Lees Knowles, and William Shrubsole were elected Fellows of the Society.—The g communications were read:—On a dredged skull of *machatus*, by Prof. W. Boyd-Dawkins, F.R.S.—On e from Mont Blanc, by Frank Rutley, F.G.S.—On ted porfido-rosso-antico, by Frank Rutley, F.G.S.—On Chlostomasious Bryozoa from Aldinga and the River Cliffs, South Australia, by Arthur Wm. Waters, The seventy-three fossils described in the present were collected by Prof. Ralph Tate, and, with a few exs, are from Aldinga and the River Murray Cliffs, ia. This collection again furnishes interesting cases of growing in both the Escharæ and the Lepralia form; but f interest is in a number of specimens which grow in a ata" manner, thus in the mode of growth resembling er. Attention was again called to the fact that, though e and nature of the zoœcial avicularia (tonychocellaria) acters of the greatest value, yet their presence or absence be made a specific distinction, as there are a large of cases where specimens are found with none or only a avicularia, whereas on other specimens of the same collected under similar circumstances, they may occur tly over the whole colony, or in parts of the colony, in mbers. In the *Challenger* Report, Mr. Busk refers to a process rising from the middle of the base of the avicumandible, and names it "columella." This he considers curs in one division of the *Cellepora*, and in this division those belonging to the southern hemisphere. This was to be by no means the case, as it is found in the es of *Cellepora sardonica* from the Mediterranean, in two mmon Mediterranean *Cellepora*, &c. In many species a denticle in this position rising from the calcareous ch divides the avicularium. This denticle occurs in genera and species, and may often be found a useful character when examining fossils. Out of the 220 ow described in this series of papers, just about one-now known living. The species noticed in this paper nty-three in number, referred by the author to the *Cellarina*, *Membranipora*, *Microporæ*, *Monoporelli*, *Steginella*, *Cribrilina Mucronella*, *Microporella*, *Lunulites*, *Lepralia*, *Smittia Schizoporella*, *Mastigophora*, *Retychopora*, *Cellepora*, *Lekythopora*, and *Salenaria*. cies are described as new, namely, *Microporella pectilli-Lepralia complexa*, *Cellepora biscuita*, *Schizoporella pre-Membranipora temperata*.

ria Institute, March 16.—Mr. W. F. James read a the relation of fossil botany to theories of evolution, he gave a résumé of the whole question with which his alt.

EDINBURGH

ematical Society, March 13.—Mr. George Thom, Vice-in the chair.—Mr. George A. Gibson read a paper t, to the construction of treating tangents to confocal conicoids. t's method of treating tangents to confocal conicoids. S. Mackay gave an account of Schooten's geometry of —Mr. A. V. Fraser read a note by Mr. F. Alexander finite integrals.

PARIS

emy of Sciences, March 9.—M. Bouley, President, buit.—Obituary notices of the late M. J. A. Serret, for Geometry, by MM. Jordan, Bonnet, Faye, and Renan.—Methods of observing the polar stars at a great distance from the meridian, with a table containing the corrective term intended to facilitate the reductions, by M. M. Loewy.—Bromuretted substitutions of the polyatomic phenols, by MM. Berthelot and Werner. Here the authors deal with resorcine ($C_{12}H_6O_4$) and orcine ($C_{14}H_8O_4$) diatomic phenols, each of which furnishes a tribromuretted substance capable of being employed in their quantitative analysis.—On the decomposing action exercised by the chloride of aluminium on certain hydrocarburets, by MM. C. Friedel and J. M. Crafts.—Report on the new gallery of palæontology in the Paris Natural History Museum, by M. A. Gaudry. This gallery, which has been fitted up in the Whale Court, contains specimens of *Megatherium Cuvieri*, *Elephas meridionalis*, *Mastodon augustidens*, *Cervus megaceros*, *Testudo elephantina*, *Polaeonanerus typus*, *Palæotherium magnum*, and some other gigantic extinct animals.—Observations of the planet 245, discovered by M. Borrelly at the Observatory of Marseilles, by M. Stephan.—On some anomalies in the phenomenon of tides in connection with M. Hatt's work, by M. de Jonquieres.—Report on the International Congress of Washington, and on the resolutions there adopted respecting the first meridian, the universal hour, and the extension of the decimal system to the measurement of angles and of time, by M. J. Janssen, representative of France at the Congress. The report, which is partly occupied with M. Janssen's address objecting to Greenwich, and advocating a neutral first meridian at the Azores or Behring's Straits, concludes with the words: "However this be, and apart from the question of the meridian, which is not yet decided, let us not forget that the accession of England to the convention for the metrical system and the wish expressed for its general extension are important results, showing that our presence in Washington has not been useless either for science or progress."—Report on M. Léauté's memoir on oscillations at long intervals in machines propelled by hydraulic action, and on the means of preventing those oscillations, by M. Phillips.—Observations of Encke's comet made at the Observatory of Paris (equatorial coudé), by M. Périgaud.—Spectroscopic studies, by M. Ch. V. Zenger. The author submits a method for clearing from the field of vision all rays except those lying nearest to the C band, and for thus observing, by means of the parallelopiped of dispersion, the protuberances proper to hydrogen under the monochromatic red light.—A method of avoiding the dangers incident to mechanical generators of electricity: reply to M. Daussin's claim to priority of invention, by M. A. d'Arsonval.—Study of the means employed to take the potential of the atmosphere: electromotor force of combustion, by M. H. Pellat.—On the decomposition of salts by water, by M. H. Le Chatelier. The author, against the generally-accepted views, formulates and demonstrates the two following propositions:—(1) The quantity of free acid required to resist the decomposition of a salt in solution increases indefinitely with the proportion of the salt contained in the fluid; (2) the decomposition of a salt in solution increases or diminishes with the changes of temperature, according as this decomposition absorbs or liberates heat.—On the separation of titanium from niobium and zirconium, by M. Eug. Demarçay.—On the normal pyrotartaric and succinic nitriles $CN-(CH_2)-CN$; and $CN-(CH_2)_2-CN$), by M. Louis Henry.—On the preparation, properties, and reactions of iodacetone, by MM. P. de Clermont and P. Chastard.—Heat of formation of the glycol bisulphide of ammoniac, by M. de Forcrand.—Researches on the colouring matters of leaves; identity of the orange-red matter with carotine, $C_{24}H_{16}O$, by M. Arnaud.—On the analogies with and differences between the genus Simodosaurus of Eggenburg, by M. V. Lemoine.—Underground rumblings heard on August 26, 1883 (date of the Krakatoa eruption), at the island of Caiman-Brac, Caribbean Sea, 20° N. lat., 83° E. long., by M. F. A. Forel.—Remarks on the three first numbers of Rossi's decennial *Bulletin* of the Observatory and central geodynamic Archives of Rome, by M. Daubrée.

BERLIN

Physical Society, February 6.—Dr. König communicated an experiment he had carried out in conjunction with Dr. Richarz, with a view to testing the ground of a misgiving expressed at a recent meeting of the Society in connection with a plan he had set forth for the purpose of determining the constants of gravitation (*vide* NATURE, vol. xxxi. p. 262). It was maintained that the lead block of 2000 centners would, on

account of its weight, become extended at its base and consequently change its form—a circumstance which would prove very prejudicial to the experiments contemplated in connection with it. Dr. König and Dr. Richarz had, therefore, calculated the pressure exercised by the lead mass, which should have a basal plane of 1·9 square metres, on the square centimetre, and had found it equal to 2·3 kg. They then prepared a small lead cylinder, placed it with due underlayers on the earth, and by means of pulleys and weights caused a constant pressure of more than 6 kg. per square centimetre to be exerted on its smooth upper surface. Two fine steel spikes were fastened in the side of the lead mass, and their distance from each other exactly measured. After this pressure had been exerted for a considerable length of time on the lead, the distance of the two steel spikes from each other was again determined, and all the displacement which had occurred was found to be but 0·01 mm., an amount which might very well have been caused by differences of temperature. At all events it was so trifling, that in the case of a pressure three times less, such as would be that of the large lead mass utilised in the quantitative experiment, no deformation due to its own weight was to be apprehended.—Dr. König further reported on measurements of colour-sense and visual acuteness effected by him on a number of Zulus at present staying in Berlin. Their colour-sense was tested by means of the lenticscope. On the turning of the Nicol prism the savages stated distinctly that the colours of the two images became even more similar to each other, and at last almost alike, and that, on a further turning of the Nicol prism, the colours came to vary more and more from each other. The colour-sensibility of the savages was, therefore, equal to that of the normal eyes of civilised peoples. They distinguished with exactness, and denoted by different names the colours red, yellow, blue, brown, black, and white. While they distinguished as red only the purest spectral red, they denoted as yellow or as blue all objects having any yellowish, or, on the other hand, any bluish tinge. As "grass colours" they called the green, and violet they named after a mineral unknown to Dr. König. The unsaturated colours they defined by affixing a syllable to the name of the particular colour in each case, an affix signifying much the same as "young." The visual acuteness was measured by means of Snellen's writing tests, according to which the smallest characters used, when distinctly seen at a distance of 6·5 m., was equal to 1. From extensive statistical investigations in Germany the visual acuteness of a perfectly normal eye was found to average 1·75. The measurements taken with male Zulu adults showed, on the other hand, that they were able to recognise with certainty the smallest written characters at a distance of from 24 m. to 25 m.; a Zuly boy of about eight years showed a visual energy of only 1·50; and a Zulu woman a still lower value of visual force—a result which was, however, to be explained by the circumstance that the woman was squint-eyed, and had, moreover, clearly-ascertained obscurations of the cornea.—Following up this address, Dr. König intimated that, in the Physical Institute, experiments had been made by Dr. Uhthoff on the influence of light intensity on visual acuteness. From a large number of experiments it appeared that if the light intensity was taken as abscissa, and the degrees of visual acuteness appertaining to it as ordinates, then the resulting curve, in the case of the greatest visual acuteness answering to a good full illumination by day, ran parallel to the axis of the abscissa, falling, at first slowly and then rapidly, towards the null point. The mode of the sinking of the curve was different with different individuals. Under low light intensities differences occurred as much as 1 to 2. The visual energy became null shortly before the light intensity was null. In this respect likewise, however, there were differences in the case of different individuals, those possessing a greater acuteness of vision showing the visual energy at the null point under a greater light intensity than in the case of such persons as had a lower acuteness of vision, in whom the curve began nearer the null point of the abscissa. Normal eyes with greater acuteness of vision, under the highest light intensities attainable by means of a petroleum lamp, showed symptoms of dazzlement, and the curve sank to the axis of the abscissa. In the case of the eyes of much less visual acuteness the curve, even under these highest intensities, continued still parallel to the abscissa. In the discussion which this address gave rise to, Prof. von Helmholtz brought out and established, by entering into detail, that it was altogether unjustifiable to assume that the ancients had not such developed colour-sense as recent peo[illegible], and that this assumption was an inference quite unwarrant[illegible] drawn from the mere defect of names for the different colours.

February 20.—Dr. Kayser referred to a method published by M. Wolf in the *Comptes Rendus* for measuring the velocity of light, which differed from Foucault's experiment inasmuch as the rotating mirror was concave and the aperture admitting the light was a small transparent spot in a larger concave mirror. By Wolf's method the displacement of the reflection of the light could be made to reach as much as 1 m., and could be easily measured with precision.—Prof. Neesen made some communications respecting an investigation which was not yet concluded, into Geissler's tubes. In an old tube with aluminium electrodes he found that the process of evacuation, up to the highest degree of rarefication, at which electricity no longer passed through the tube, was rendered more difficult if continuous electric discharges were sent through the tube, but, on the other hand, was very easy when no electric current was transmitted. If, with high degrees of rarefication, phosphoric light filled the glass ball, a black precipitate was regularly formed on the glass, which disappeared on the admission of a small quantity of air into the tube. If the tube was put in communication with an electric lamp, and the carbon thread, after being kept in a glowing state for about an hour, was allowed to cool, a complete vacuum was most easily obtained, probably because the gaseous substances adhering to the glass were absorbed by the carbon. In such a case it was of no consequence for the evacuation whether a discharge was transmitted continuously through the tube or not. The phosphoric light, after the absorption by the carbon-thread, was likewise changed. Instead of being yellow and filling up the whole ball, it was rosy, limited, and soon disappeared. If the tube was then for some time exposed to the air and evacuated, yellow phosphoric light and the black precipitate again appeared. Prof. Neesen was of opinion that the process of phosphorescence was induced by substances which were absorbed by the glass and decomposed by the electric light, and that the black precipitate was a product of this decomposition.—Dr. Sklarek referred shortly to the measurement of the propagation velocity of electricity in telegraph wires, which Prof. Hagenbach, in Basel, had carried out according to a new method.

Diary of Societies

LONDON

THURSDAY, MARCH 19.

AL SOCIETY, at 4.30.—On Transfer-Resistance in Electrolytic and ilaic Cells: Dr. Gore, F.R.S.—Note on Rev. Robert Harley's Paper, Prof. Mallet's Classes of Invariants identified with Sir James Cockle's ticonds": Prof. J. C. Malet, F.R.S.—On the "Paralytic" Secretion of iva: J. N. Langley, F.R.S.

EAN SOCIETY, at 8.—New Genera and Species of Hydroids from H. tty's Collection: Prof. Allman (postponed from March 5).—Plants of ersley, Bastlick, O'Neill, and Margaret Islands, South-East New inea: Wm. E. Armit.

MICAL SOCIETY, at 8.—On the Presence of Cholin in Hops: F. Griess.

ons INSTITUTION, at 7.—Pianoforte Composers after Beethoven's Time: of. Ernest Pauer.

AL INSTITUTION, at 3.—The New Chemistry: Prof. Dewar.

FRIDAY, MARCH 20.

AL INSTITUTION, at 9.—Liquid Films: Prof. A. W. Rücker.

SATURDAY, MARCH 21.

AL INSTITUTION, at 3.—Richard Wagner: C. Armbruster.

MONDAY, MARCH 23.

AL GEOGRAPHICAL SOCIETY, at 8.30.—Geographical Notes on Herat, the Valleys of the Hari-Rud and Murghab: Major T. H. Holdich, E., of the Afghan Boundary Commission. With Introduction by neral J. T. Walker, R.E., late Surveyor-General of India.

TY OF ARTS, at 8.—Carving and Furniture: J. Hungerford Pollen.

TUESDAY, MARCH 24.

ROPOLOGICAL INSTITUTE, at 8.—The Inhabitants of New Ireland and its chipelago: A. J. Duffield.—On Methods of Testing the Sight of Civilised Savage Peoples.—(1) by R. Brudenell Carter, F.R.C.S.; (2) by C. berts, F.R.C.S.

AL HORTICULTURAL SOCIETY, at 1.—Scientific Committee.

AL INSTITUTION, at 3.—Digestion and Nutrition: Prof. Gamgee.

WEDNESDAY, MARCH 25.

LOGICAL SOCIETY, at 8.—On the Relationship of Ulodendron, Lindley d Hutton, to Lepidodendron, Sternberg; Bothrodendron, Lindley and tton; Sigillaria, Brongniart; and Rhytidodendron, Boulay: Robert dson.—On an almost Perfect Skeleton of Rhytina antiqui obtained from Pleistocene Peat-deposits on Behring's Island by Mr. Robert Damon: ry Woodward, F.R.S.

TY OF ARTS, at 8.—Introduction of the Beet Sugar Industry into gland: Col. Sir F. Bolton.

THURSDAY, MARCH 26.

AL SOCIETY, at 4.30.

TY OF TELEGRAPH ENGINEERS, at 8.—On the Seat of Electromotive ce in a Voltaic Cell: Prof. Oliver J. Lodge, D.Sc.

AL INSTITUTION, at 3.—The New Chemistry: Prof. Dewar.

FRIDAY, MARCH 27.

AL INSTITUTION, at 9.—The Motor Centres of the Brain, and the chanism of the Will: Prof. Victor Horsley.

SATURDAY, MARCH 28.

ICAL SOCIETY, at 3.—On Calculating Machines, illustrated by a Col- ion of Ancient and Modern Machines lent by their owners for the asion: Jos. Edmondson.—Exhibition of Instruments by Prof. Kennedy, E. D. Malcolm, Conrad C. Cooke, and A. Hilger.

AL INSTITUTION, at 3.—Richard Wagner: C. Armbruster.

AL INSTITUTION ASSOCIATION, at 3.—Visit to the Geological Museum of Dr. J. nning Pearce, Manor House, Brixton Rise.—Demonstration by F. W. ller, on Mnemonic Formulæ.

e SUB-EDITORSHIP of "NATURE"

VACANT. Candidates must possess a knowledge of German and horthand.—Application, with Testimonials, to be sent to the Publishers NATURE, 29, Bedford Street, Strand, W.C.

NSHINE RECORDERS.—For UNI-

ERSAL and for FIXED LATITUDES—fitted with Prof. Stokes olarical Fringe, as adopted by GOVERNMENT, the METEORO- OGICAL COUNCIL, and many private Observatories. Price Seven Twelve Guineas; 400 Cards, 32s.—Apply to R. J. LECKY, care of IRELAND; CORK & CO., Northumberland Street, Strand. Full Trade iscount.

OKS (Secondhand), Miscellaneous, Re-

inders, &c.—C. HERBERT, English and Foreign Bookseller, 319, owell Road, London, E.C. Catalogue free on receipt of two stamps. braries, Old Books, and Parchment purchased.

SANDERSON & Co.,

Sole Inventors of the Solid Copper Tape

LIGHTNING CONDUCTOR

In Continuous Lengths, without Joints, as supplied by them to Her Majesty's Government and the Colonies; the Italian Government, the Argentine Republic, and other Foreign Governments; the Royal Courts of Justice, Strand the Houses of Parliament, &c.

The Jury Commission, acting on the Reports of the International Juries of the Health Exhibition, have awarded a Bronze Medal to Class 26 to Messrs. SANDERSON & Co. for their Solid Copper Tape Lightning Conductors in Continuous Lengths, without Joints, and of High Conductivity Copper.

LEADENHALL HOUSE, 121, LEADENHALL STREET, E.C.

SECOND EDITION,

GRIFFIN'S CHEMICAL HANDICRAFT.

PRICE 4s. 9d. POST FREE.

A CATALOGUE OF CHEMICAL APPARATUS,

ILLUSTRATED, CLASSIFIED, DESCRIPTIVE.

Demy 8vo, 480 pp., Illustrated with 1,600 Woodcuts.

Most Complete and Cheapest List of Apparatus.

JOHN J. GRIFFIN AND SONS, 22, GARRICK STREET, LONDON, W.C.

S. N. STOUT.

In Casks, 12/6 per 9 gals. In Bottle, 3/3 per doz. Impl. Pts.*

* Bottles charged 2/- per doz., and allowed at the same rate if returned; but they must be paid for with the Beer.

Neither sugar, saccharum, nor any of the many new Brewing Materials are used in the manufacture of the "S. N." Stout; it is Brewed entirely from the finest Malt and Hops; it is, too, more hopped than Stout is generally; therefore, besides being very nutritious, it is an excellent Tonic and particularly suited for invalids, ladies nursing, or anyone requiring a good strengthening beverage. It is a "Sound Nutritious" Tonic, and very much recommended by Medical men.

WALTHAM BROTHERS,

Revised Catalogue sent on application to R. & J. BECK, 68, CORNHILL.

The REMINGTON "PERFECTED" TYPE-WRITER.

A MACHINE to supersede the pen for manuscript writing, correspondence, &c., having twice the speed of the pen: is always ready for use, simple in construction, not liable to get out of order, easily understood. It is used in Government Offices, and by Merchants, Bankers, Lawyers, Clergymen, Doctors, Scientists, &c.

"The other advantages of the machine, those for which chiefly I personally value and employ it, are worthy of a moment's consideration. Its work in my hands is about twice as rapid as that of a pen, and became so after a few weeks of practice. I have worked the machine for eight consecutive hours without more than ten minutes' interruption, and at the end of that time my hands were not conscious of the least fatigue. Every writer is aware that the same thing cannot be said with regard to the pen.—ROBERT BRUDENELL CARTER, F.R.C.S., &c."

No. 2 PERFECTED TYPE-WRITER. CAPITALS AND SMALL LETTERS.

REDUCED PRICES.

The Times, Tuesday, September 12, 1882, said: "The chief use of the type-writer seems to be for business correspondence, where rapid and legible copying, as for the transcription of short-hand notes, and in the preparation of manuscript for the press or for revision. . . .

"In the preparation of manuscript for revision or for the press, the advantages of the type-writer over the pen are very decided. There is, first, the greater rapidity of production; and next, the superior quality of the product. The work of the type-writer is comparable to a printed proof, and may be looked and revised with the same facility, the necessary alterations being made by hand with a pen. . . . Manuscript made by the type-writer ought to give to the printer almost precisely the conditions in which it finally appears."

BEEMAN & ROBERTS, Sole Agents, 6, King Street, Cheapside, London.

ASK FOR **BRIERLEY'S "BEAU IDEAL" SPRING BRACE**

CANNOT BREAK OR RUST.

Easiest for SHOOTING, RIDING, and GENERAL WEAR.

MORY and SUCCESS.—What contributes to success? A good memory.—What can all obtain from Prof. Loisette's DISCOVERIES? A good memory—THE PHYSIOLOGICAL ART OF NEVER FORGETTING—using none of the "Links," "Pegs," "Localities," or "Associations" of Mnemonics. Lost memories restored—the worst made good, and the best better. *Any book learned in one reading.* Prospectus POST FREE, giving opinions of Mr. RICHARD A. PROCTOR, Dr. ANDREW WILSON, and others who have studied the System. A Day Class in Never Forgetting and the Cure of Mind-Wandering commences every Monday at 3 p.m. An Evening Class every Tuesday at 8 p.m. Lectures in Families (if the locality) also taught thoroughly by POST. Prof. LOISETTE, 27, NEW OXFORD STREET (opposite Mudie's), W.C.

RIBBON METHOD OF CUTTING SECTIONS.

The Cambridge Scientific Instrument Company have designed a new and improved Microtome for cutting continuous Ribbons of Sections on the plan first introduced by Mr. Caldwell. The new instrument has the advantage over the original pattern of dispensing with the vaulted hand altogether, and consequently not only avoiding the troubles of lifting the series of Sections from the knife, but also of allowing them to fall on to the glass slide in their proper position for mounting. Although the instrument costs only one-sixth the price of the original pattern, it will be found to do all that is required, and to possess the additional advantage of dispensing with the more complex and delicate adjustments. Price of the Microtome, £3 3s.

CAMBRIDGE SCIENTIFIC INSTRUMENT CO.,

ASTRONOMICAL TELESCOPE

With 2-inch Achromatic Object-Glass of excellent quality, with brass body, one Terrestrial and two Celestial Eyepieces, in Case complete. Guaranteed to be capable of dividing Double-Stars and showing Saturn's Ring and Jupiter's Belts.

Price £6 10s. 0d.

ONDON HOSPITAL AND MEDICAL COLLEGE,
MILE END, E.

e SUMMER SESSION will commence on Friday, May 1. Intending nts are advised that under the new regulations of the Royal College ysicians and the Royal College of Surgeons, it is exceedingly advan- us to enter for the Summer Session. Students now entering are also le for the Entrance Scholarships in September.
e Hospital contains nearly 800 beds, and is the largest general Hospital eat Britain.
neral Fee for Lectures and Hospital Practice, 90 guineas in one sum, or uineas in three instalments. The Resident and other Hospital Appoint- s are free to full Students.
ecial entries may be made for Medical and Surgical Practice, also for the e of Practical Surgery.
e London Hospital is now in direct communication by rail and tram with rts of the Metropolis, and the Metropolitan, Metropolitan District, n Eastern, and East London Railways have stations within a minute's of the Hospital and College.
r Prospectus and particulars apply to

MUNRO SCOTT, Warden.

NIVERSITY COLLEGE, LONDON.
CHEMICAL PHYSICS AND INORGANIC CHEMISTRY.
erly Lectures will be given by SAMUEL RIDEAL, B.Sc., F.C.S., on days, Wednesdays, and Fridays at 4, commencing April 27.
e Course includes the Subjects for the Inter. Sci. and Prel. Sci. ors' Examinations, but some knowledge of the pass work will be ired. Fee £2 2s.

ALFOURD ELY, M.A., Secretary.

PRELIMINARY SCIENTIFIC AND INTERMEDIATE
IENCE EXAMINATIONS OF THE UNIVERSITY OF LONDON.
OLOGY.—A Course of Twenty Lectures and Forty days Practical , dealing with the Zoological Portion of the University Pass Schedule r the direction of Prof. Lankester, will commence on May 5, at Uni- y College, Gower Street. Practical Work:—Monday, Tuesday, Wed- ay, Thursday, from 2 to 5. Lectures: Tuesdays and Thursdays from . Fee, Seven Guineas for both.
R.—A Course of Lectures and Twenty Days' Practical Work in the ond portion of the University Pass Schedule is conducted during May, and July, by Prof. Oliver. Apply at the College for further infor- on.

ANTED.—"NATURE," "CHEMICAL NEWS," and the "ELECTRICIAN," week after publication. Half- Price.—R. L. T., 24, Penn Street, Hr. Broughton, Manchester.

MINERALOGY AND GEOLOGY.
. HENSON'S Latest Arrivals are —
y. Fine DOUBLY-TERMINATED CRYSTALS of ZIRCON, ches long, 1½ square; BERYLS, DIOPTASE, UWAROWITE, UEWITE, NATIVE SILVER, HERDERITE, Very Brilliant LILES, CHALCOSIDERITE and NATIVE COPPER, Cor- POLISHED JADE and GREEN AVENTURINE, GROUPS SINGLE CRYSTALS of STIENITE, Japan; "SHERRY" OUKED TOPAZES, Siberia.
Large Series of ROCKS, also MICROSCOPIC SECTIONS of the
Lists on Application Hammers, Chisels, and Hammer Straps.
IVATE LESSONS AND EVENING CLASSES.
BLOWPIPE CASES AND APPARATUS. Catalogues free.
SAMUEL HENSON,
277, STRAND, LONDON,
Opposite Norfolk Street.

IENCE AND ART DEPARTMENT
EB CENT. GRANT FOR THE PURCHASE OF STANDARD LECTIONS AND APPARATUS FOR TEACHING GEOLOGY MINERALOGY. NEW LISTS and FORMS on which the ication is to be made supplied by
THOMAS J. DOWNING,
Geologist, &c.,
HISKIN STREET, LONDON, E.C. (over Quarter of a Century).

NSHINE RECORDERS.—For UNI- VERSAL and for FIXED LATITUDES—fitted with Prof. Stokes Zodiacal Frame, as adopted by GOVERNMENT, the METEORO- LOGICAL COUNCIL, and many private Observatories. Price Seven Twelve Guineas; 200 Cards, 2s.—Apply to R. J. LUCKY, care of IRELAND, COFE & Co., Northumberland Street, Strand. Full Trade Discount.

HOW & CO.'S
blogical Transparencies for the Lantern.
Descriptive Catalogue on Application.
VALKER'S SPECIFIC GRAVITY BALANCE FOR ROCKS AND MINERALS.
HOW & CO.'S POCKET MICROSCOPE LAMP, 1s. 6d.
CRO-PETROLOGY.—Sections of Pitchstones, Obsidians, Granites, ites, Diorites, Gabbros, Dolerites, Basalts, Tachylites, Trachytes, ites, Porphyrites, Rhyolites, Lavas, Ashes, Gneiss, Schists, Lime- ites, Porphyries, price 1s. 6d. each.
s, &c., price 1s. 6d. each.
JAMES HOW & CO., 73, FARRINGDON STREET, LONDON.

LIVING SPECIMENS FOR THE MICROSCOPE.
GOLD MEDAL awarded at the FISHERIES EXHIBITION to
THOMAS BOLTON, 57, NEWHALL STREET, BIRMINGHAM;
who has last week sent to his subscribers Balanus balanoides, in the Nauplius or other early larval stages, with drawing and description. He has also sent out Lophopus crystallinus, Cordylophora lacustris, Spongilla fluviatilis, Gomium pectorale, Vulvox globator, Diatoms and Desmids; also Hydra, Amœba, Vorticella, Crayfish, and other Specimens for (Huxley and Martin's) Biological Laboratory work.
Weekly Announcements will be made in this place of Organisms T. B. is supplying.
Specimen Tube, One Shilling, post free.
Twenty-six Tubes in course of Six Months for Subscription of £1 1s., or Twelve Tubes for 10s. 6d.
Portfolio of Drawings, Ten Parts, 1s. each.

Sales by Auction.
Birds in Cases and Bird Skins.
MR. J. C. STEVENS will SELL BY AUCTION, at his Great Rooms, 38, King Street, Covent Garden, on MONDAY and TUESDAY, March 30 and 31, at half-past 12 o'clock precisely each day, the COLLECTION of BIRDS in CASES and BIRD SKINS formed by F. Raine, Esq., of Durban. The birds, with very few exceptions, were all obtained in the flesh, and are beautifully stuffed and mounted in plain white cases, nothing being put in to hide the defects or to attract the eye from the bird. The collection also contains a few rare and well-stuffed animals, which will be included in the sale.
On view from Ten till Four the Saturday prior and Mornings of Sale, and Catalogues had.

INTERNATIONAL HEALTH EXHIBITION.
DIVISION—EDUCATION.
A PRIZE MEDAL AWARDED TO
THOMAS D. RUSSELL,
78, NEWGATE STREET, LONDON, E.C.,
For Geological Collections for Science Teaching.
Catalogues Post Free.

LANTERN READINGS.—DISSOLVING VIEWS.
THE NEW QUADRUPLICON.
New Season, 1884 and 1885.—Popular Subjects for this Season.
The Channel Islands—The War in the Soudan—The River Thames—Devonshire Scenery—Hereford and the River Wye—The English Lakes—London Poor and How They Live—Egypt and the Nile Expedition—Norway—The Lifeboat—The Signal Box—The Maids of Lee—Poor Pa's Trousers—Shadows on the Blinds, &c.
The largest and newest Stock of Lanterns and Slides, Scientific and General, on Hire and Sale in this country at the Lowest Prices.
E. MARSHALL, 35, Queen Victoria Street, London, E.C.

C. D. AHRENS.
PRISM WORKER AND PRACTICAL OPTICIAN,
36, GREAT RUSSELL STREET, LONDON, W.C.
SPECIAL NOTICE—See the New Polarising Prism.
Can be used over any A & R Eyepiece. Strongly recommended for Lantern Work; will take in any Object. Also see the New Erecting Microscope. Any Object-Glass and any Eyepiece can be used with it. It is the only way of seeing the Objects in their right shape and form. Maker of the Largest Nicol Prisms in existence for the Late W. Spottiswoode, Esq., F.R.S., &c., &c., and for Frank Crisp, Esq., LL.B., B.A., &c., &c.
TRADE SUPPLIED WITH PRISMS.

MICROSCOPIC OBJECTS FOR HIRE,
Histological, Botanical, Geological, by the best Monsters. Let out on most moderate terms. Particulars of B. WELLS, Dalmain Road, Forest Hill.

SIX PRIZE MEDALS
AWARDED FOR GEOLOGICAL COLLECTIONS.
Geological Collections especially adapted for Teaching as supplied to Science and Art Department, and used by all Lecturers and Teachers in Great Britain, &c.
New and Rare Minerals constantly arriving from all parts for collection or Single Specimens.
ROCK SECTIONS AND ROCK SPECIMENS:
The Largest Variety in England.
New Catalogues and Lists on application to—
JAMES R. GREGORY,
88, CHARLOTTE STREET, FITZROY SQUARE, LONDON.
Established 17 Years in London.

MUTUAL LIFE ASSURANCE.

SCOTTISH PROVIDENT INSTITUTION.

EDINBURGH—6, ST. ANDREW SQUARE. LONDON OFFICE—17, KING WILLIAM STREET, E.C.

The ATTENTION of ASSURERS is directed to the SPECIAL ADVANTAGES obtainable in this Society, in respect of ECONOMY—EQUITY—SAFETY.

ECONOMY.—The Premiums are, in many cases, 20 to 25 per cent. under the usual rates, so that a Policy for £1200 may generally be had for the yearly payment which would elsewhere assure £1000 only.

EQUITY.—The whole Surplus is divisible among the Policy-holders themselves, on an equitable principle—no dues being given to those by whose early death there is a *loss* to the other Members. From this source large additions have been made, and may be expected in the future.

SAFETY.—The Business (which for ten years has exceeded a Million yearly) is of the most select character, and conducted at the smallest cost.

The expenses, which are less than in any Office transacting so large a business, were last year under 9 per cent. of the Premiums, and little over 6 per cent. of the year's Income.

THE FUNDS accumulated from Premiums exceed **£5,000,000**, the increase last year being **£333,383**.

Only two Offices in the Kingdom (both older) have as large a Fund.

Claims under Policies now payable a Month after Proof.

Reports, with Tables of Premiums, &c., on Application.

J. MUIR LEITCH, London Secretary.

JAMES WATSON, Manager.

TEXT-BOOKS OF SCIENCE.

PRACTICAL PHYSICS.

By R. T. GLAZEBROOK, M.A., and W. N. SHAW, M.A., Demonstrators at the Cavendish Laboratory, Cambridge, with 62 Woodcuts.

Fcap. 8vo. Price 6*s.*

"Here is a work that has really been much wanted by students and teachers engaged in physical laboratories. . . . So far as we know there is no similar work in existence. . . . Teachers will find the volume of special value to them; while students, particularly those who have not a demonstrator to appeal to, will find many of their difficulties removed by a careful perusal of its pages."—*English Mechanic.*

London: LONGMANS, GREEN & CO.

THE ZOOLOGIST:

A MONTHLY MAGAZINE OF NATURAL HISTORY.

Third Series. Edited by J. E. HARTING, F.L.S., F.Z.S., Member of the British Ornithologists' Union; contains—

Original Articles by well-known naturalists in every branch of zoology; habits of animals; arrival and departure of migratory birds; occurrence of rare birds; distribution and migration of British fresh-water fish; new or rare marine fish; local aquaria; British reptiles; British land and fresh-water molluscs, with remarks on the haunts and habits of the species; and other matters of general interest to those who delight in natural history. Reports of the Linnean, Zoological, and Entomological Societies. Reviews of natural history books. Occasional translations from foreign zoological journals of important and interesting articles in various branches of zoology. There are occasional woodcuts.

JOHN VAN VOORST, 1, Paternoster Row.

NORTH BRITISH AGRICULTURIST,

the only Agricultural Journal in Scotland, circulates extensively among Landowners, Farmers, Resident Agents, and others interested in the management of land throughout the United Kingdom.

The AGRICULTURIST is published every Wednesday afternoon in time for the Evening Mails, and contains Reports of all the principal British and Irish Markets of the week.

The special attention of Land Agents is directed to the AGRICULTURIST as one of the best existing papers for Advertising Farms to be Let and Estates for Sale.

Advertisers addressing themselves to Farmers will find the AGRICULTURIST a first-class medium for reaching that Class.

Price 3*d.* By post 3½*d.* Annual Subscription, payable in advance, 14*s.* Offices—377, High Street, Edinburgh; and 145, Queen Victoria Street London, E.C.

Money Orders payable to CHARLES ANDERSON, Jun., Edinburgh.

LA SEMAINE FRANÇAISE: a Weekly

Newspaper and Review in the French Language. Politics, Literature, Science, Art, Varieties, Notes. Price 2*d.*, through Booksellers, and at the Railway Bookstalls. Office, 441, Strand, W.C.

LA SEMAINE FRANÇAISE: Journal Français pour l'Angleterre: Politique, Littérature, Sciences, Arts, Variétés, Nouvelles, et Notes. Un exemplaire par la poste, 2½*d.*, en timbres poste. Abonnement franco par la poste—un an, 10*s.* 10*d.*; six mois, 5*s.* 5*d.* Prix 2*d.* chez tous les libraires et aux gares des chemins de fer. On s'abonne aux bureaux, 441, Strand, Londres, W.C.

LA SEMAINE FRANÇAISE.—"La Semaine Française" has been brought out in London for the benefit of those English readers who may wish to study contemporary French from all points of view, instead of confining their reading to one particular Gallic print. It certainly merits success."—*Graphic.*

THURSDAY, MARCH 26, 1885

PRACTICAL PHYSICS

ractical Physics. By R. T. Glazebrook, M.A., F.R.S., and W. N. Shaw, M.A., Demonstrators at the Cavendish Laboratory, Cambridge. (London: Longmans, Green, and Co., 1885.)

THE authors have done a real service to all whose business it is to conduct classes in a physical boratory by supplying them with a most excellent iide. Not only teachers, but students, will find this ook invaluable.

The authors have for some time prepared manuscript ites for use in the laboratory, sufficient to enable a udent to make the measurements described without that equent necessity for supervision which is found when rbal instruction only has been given. Since such well sted notes form the main portion of this work, it is cerin that the experiments which are described have been so equently carried out that the details given are sure to correspond to the best arrangement in each case, and further, at all possibility of an oversight has been removed.

In many cases instruments used for the same purpose e so different in d tail that the authors were met by the fficulty of choosing whether to describe several forms to be content with explaining the particular instrument ed for each purpose at the Cavendish Laboratory. hey have, in adopting the latter course, found one eans of limiting an enormous subject. In another direcn they have found a natural boundary—that between a ook of theoretical and one of practical physics. The eory of the methods and instruments is not given at ngth, except in those cases where the text-books are not fficiently explicit. Again, the whole range of practical hysics is so extensive that choice had to be exercised as what experiments should be included and what unoidably passed by. The experiments selected in each bject are typical, and are such as "to enable the student make use of his practical work to obtain a clearer and ore real insight into the principles of the subjects; they clude those which have formed for the past three years e course of practical physics for the students preparing r the first part of the Natural Sciences Tripos." It ould be impossible to make a selection more exactly uited to meet the wants of an educational laboratory.

In the preface will be found the system employed at he Cavendish Laboratory for making a set of apparatus o as far as possible with a large class. The subject is ivided into sections, each requiring its own instruments; ometimes one, sometimes several, experiments belong to ne section. When any section is assigned to a student, one of the instruments belonging to it are available lsewhere. The same system of division is employed in he text, no less than eighty-two numbered sections being he result.

The value of the book is much enhanced by the addition, at the end of each section, of the results of an ctual experiment. These short statements are valuable n many ways. In the first place, they show how to enter esults systematically, so that the meaning of the entry is bvious. Secondly, they show the probable degree of accuracy attainable, especially when more than one method of making the same determination is given. Thirdly, and this is perhaps the most important to the teacher, the series of numbers to be found enables any one to discover the proportions and sizes of the several parts of each piece of apparatus employed. An example taken from p. 420 will make this clear:—

"*Experiment.*—Determine the difference of potential between the two ends of the given wire through which a current is flowing. Enter results thus:—

	grms.
Mass of water	24·2
Water equivalent of the calorimeter ...	4·2
m	28·4
M (copper deposited in voltameter)...	·222

Total rise of temperature for each two minutes:—

4°·4	4°·4	4°·2	4°·0	3°·8

T ... ... 24°·8

$E = 4·36 \times 10^8 = 4·36$ volts."

In this case there is no means of estimating the probable accuracy of the result, but the data are sufficient to enable any one who wishes to do so to reproduce exactly the instrument employed.

The chapter on physical arithmetic, in which errors, corrections, accuracy, and the manipulation of small quantities are treated, is of special value.

The chapter on the balance is very complete. Though perhaps the balance is the most important of all philosophical instruments, it is a question whether so much space as twenty pages should be devoted to it, where so much that is important is necessarily excluded for want of space. Students do certainly use the balance most blindly, and if its theory is not explained in a satisfactory manner in the text-books, this surely is the place to find it. Other subjects of which the usual accounts in the authors' opinions needed supplementing are measurement of fluid pressure, thermometry, calorimetry, and hygrometry.

The chapters on electricity and magnetism are treated in a different manner from the rest of the book, for what reason is not apparent. The precise and quantitative relations between mechanical, magnetic, and electrical units are to be found in almost every modern text-book, and so there would be no occasion to repeat definitions, &c., if the treatment of these last chapters was the same as that employed in the earlier ones. It is here perhaps more than anywhere that the authors had to exercise their choice of the most suitable, out of an almost endless variety of experiments, any one of which might well find a place. No one can find fault with the selection, yet it seems a pity that not a word is said about electrometers or indeed about statical electricity at all. Many will be disappointed in finding no account of the absolute determination of electromotive force by any of the methods of induction. The only method given depends on the measurement of the heat generated by a current, which of course involves a knowledge of the value of J, the mechanical equivalent of heat. This is the more to be regretted, as instructions for determining experimentally the value of J are not to be found in the chapter on heat. It is to be hoped that in another edition a few pages will be devoted to one or both of these essential measurements.

For a first edition the book is remarkably free from

misprints, the only one discovered being the omission of a "π" in the denominator of the expression for the absolute capacity of a condenser (p. 480). C. V. B.

MALAYAN ANTIQUITIES

Alterthümer aus dem Ostindischen Archipel und Angrenzenden Gebieten. Herausgegeben von Dr. A. B. Meyer. (Leipzig, 1884.)

THE present sumptuous volume forms the fourth of the series being issued under the enlightened management of the Curator of the Dresden Zoological and Anthropological Museum. These costly publications, which could scarcely be undertaken without the active co-operation of the general administration of the royal artistic and scientific collections in the Saxon Capital, will, when completed, prove a great boon, especially to students of eastern antiquities, and of the progress of human culture amongst the peoples of Southern Asia.

This fourth part, so far complete in itself, will be found of great value in elucidating the civilising influences both of Brahmanism and Buddhism on the races of Further India and the Malay Archipelago. It comprises nineteen photographic plates in folio, four of which are exquisitely coloured, with explanatory text and a map devoted almost exclusively to this important subject. Thus we have here embodied at once a descriptive and illustrated record of the archæological treasures in the Dresden Collection, which serve to mark the progress of the arts in the Eastern Archipelago and neighbouring regions from the earliest historic period, that is, from the first contact of those lands with the Indian religious and artistic world.

The arrangement is thoroughly systematic and most convenient for purposes of reference and comparative study, objects in stone, metal, wood, porcelain, and allied materials being grouped separately, and dealt with in the order indicated. The four stone figures from Java, reproduced on the first two plates, show at once the advantage of this arrangement. Here we have on Plate I. a genuine Brahmanical Trimurti placed side by side with a full-breasted female figure of undoubted Buddhistic type; on Plate II. an unmistakable Brahmanical Siva, again contrasted with the representation in high relief of two men, who, from their devout attitude and other indications, are evidently of Buddhist origin. Taken collectively these two groups thus present a striking illustration of both streams of Hindu culture, by which the island of Java was successively flooded. On this point the Curator's remarks in the accompanying text are highly instructive:—

"The Hindu antiquities found in Java are either Brahmanistic, Buddhistic, or mixed. Brahmanism repeatedly occurs in its Sivaistic phase. Buddhism, pure only in Borobudur and Tyandi Mendut ('Veth,' Java, ii. 172), is found mixed with Sivaism, Sivaistic divinities sometimes surrounding images of Buddha (Leemans, 'Borobudur,' 44), Buddhistic figures at others encircling Sivaistic idols ('Veth,' ii. 103, 173), or else assuming monstrous forms, such as often characterise Brahmanical deities ('Veth,' ii. 96, and Max Uhle, 'Descriptive Catalogue in MS. of the Royal Ethnological Museum,' No. 1464)."

The greatest monuments of Buddhism appear to be concentrated mainly in the central parts of Java, while those of the Brahmanical cult are scattered round them in all directions. Extensive Brahmanical settlements had already been formed in the island long before the first arrival of the Buddhist missionaries, who, according to Dr. Meyer, made their appearance probably about the fifth century of the new era. The stupendous Buddhist temple of Borobudur, rivalling that of Angkor-Vat in Camboja, is assigned to the eighth or ninth century. [illegible] no attempt has been made to determine the date of the earliest Brahmanical remains in Java or the other islands of the Archipelago. They cannot, however, be much more recent than the first century of the Christian era, and are possibly be some two or three centuries earlier. It is to be regretted that this point cannot be determined with some approach to accuracy, for it has obviously a most important bearing on the question of the migrations of the Indonesian races, and especially on the diffusion of the Malayo-Polynesian languages throughout the Indian and Pacific Oceans. Those writers, who are disposed to regard these as comparatively recent events, should at least bear in mind that there are practically no traces of Sanskrit or Prakrit elements either in Malagasy, or in any of the Eastern Polynesian dialects. Hence, if Malacca be taken as the point of dispersion west to Madagascar, east to the South Sea Islands, the migrations must necessarily have taken place at some time before the spread of Hindu influences throughout the Eastern Archipelago.

However, the collection is not confined to Hindu objects, and on Plate VII. are figured a large number of iron spear-heads, some of which are undoubtedly subsequent to the introduction of Islâm in the thirteenth century. Many of these objects, which were found at Jokjokarta (Java), are of simple type, much disorded by rust, and no doubt of considerable antiquity. But some show distinct traces of damaskeening, an art unknown before the arrival of the Arabs, although now universally diffused throughout the Archipelago. The process, [illegible] known by the name of *pamor*, consists in marqueting steel and iron by means of acids, the designs being [illegible] by the priests (Pfyffer, "Sketches from Java," p. 32).

Conspicuous among the bronze objects is a magnificent lion's head of absolutely unique type and great size [illegible] pass round neck 34 cm., diameter 30 cm., weight [illegible] kilograms), apparently from Camboja, although found in Java. This superb bronze, whose analysis yielded copper 92·49, tin 5·53, lead 1·40, cobalt and nickel 0·07, iron 0·12, total 99·61, is referred by Dr. Meyer to the flourishing period of Cambojan art as embodied in the monuments of Angkor Vahi, and would accordingly be some 600 or 800 years old. Front and side views are here given in half the natural size on two separate plates. From these it is evident that the lion is playing the part of a rakshasa or guardian to some Buddhist shrine, such as are found sculptured at Borobudur. Another relic of a very different character is a wooden figure of Garudha from the island of Bali, reproduced by the new photographic process, which has already rendered such valuable services to the arts, and especially to archæology in Germany. Here Garudha is represented as a winged human figure bearing on his shoulders probably a Vishnu, of which the legs alone, suspended in front, have been preserved. It is described as perhaps a Sivaitic representation of some Brahmanical temple in Bali, where Vishnuism and Sivaism are said to be intimately associated. The introduction of the Hindu cult into Bali, where it still [illegible]

nd in the midst of Islâm, is referred to the beginning
e fifteenth century. But the fair state of preservation
is wooden image bespeaks a much more recent date.
n the concluding plates are figured numerous designs
onze drums or gongs from every part of the Archi-
go and Further India. These instruments, which
so large a part in the social economy of the Indo-
n and Indo-Chinese peoples, are here brought to-
er for the purpose of elucidating the obscure and
rto little studied history of their origin and diffusion
ghout South-Eastern Asia. Those interested in the
ct will find much instructive matter embodied in the
mpanying text.

word of thanks is also due to Dr. Max Uhle, the
tor's able assistant, not only for his general co-
ation, but more especially for the great care he has
wed on the map of the regions in question. On
e accurately indicated all the places in Malaysia
e Hindu antiquities have at any time been dis-
ed, or where monuments dating from pre-Muham-
n times are found. A. H. KEANE

OUR BOOK SHELF

Antananarivo Annual and Madagascar Magazine, . VIII. Christmas, 1884. (Antananarivo: Printed he London Missionary Society's Press by Malagasy nters.)

HOUGH the previous number of this interesting dical was, I believe, noticed in NATURE, I should call attention to the present issue, inasmuch as it oken of the valuable scientific work which, amid difficulties, is being bravely carried on by Christian ons in the sorely troubled island of Madagascar.

e of the editors of the *Annual*, the Rev. R. Baron, accomplished botanist, indefatigable in his efforts to re the botany of his adopted home, and unwearied efforts to obtain materials for Mr. J. G. Baker and workers at home; and his colleagues, no less than lf and his fellow editor, the Rev. J. Sibree, seem ed to the double duty of teaching the Christian n and civilisation to the Malagasy and of advancing ientific knowledge of the strange land in which they r the time being dwelling.

present number, besides a spirited account of a Kabary or coronation ceremony, contains valuable gical articles on the Malagasy pronouns, by the L. Dahle; on Malagasy dictionaries, by the Rev. Cousins; and on the want of new words in the asy language and the way of supplying them, by v. S. E. Jorgensen, the latter having a more than gical, indeed a personal, interest to scientific , who, like the Madagascar missionaries, are con- in "want of new words" and not always very s in their "way of supplying them." Articles on asy superstitions, on the Sakalava, and on Mala- proverbs, contain much valuable matter for the pologist; while a paper on medical mission work, on-professional; an instructive critical exposure of raphical fiction, by the Rev. R. Baron; a four years' history, by the Rev. J. Richardson; and various of rainfall, by the Rev. J. Richardson; and various such as one recording the arrival, on Malagasy of worn fragments of pumice-stone, supposed o n Krakatoa, complete the number.

technical printing does great credit to the native s, for, though one German quotation has gone a rong, the press errors are otherwise exceedingly

I am sure that I may bespeak the sympathy of the readers of NATURE with the *Antananarivo Annual*, and that we may look forward with confidence to much scientific as well as other fruit from the continued labours of the editors and their *confrères*. M. FOSTER

LETTERS TO THE EDITOR

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts. No notice is taken of anonymous communications.

[The Editor urgently requests correspondents to keep their letters as short as possible. The pressure on his space is so great that it is impossible otherwise to insure the appearance even of communications containing interesting and novel facts.]

The Forms of Leaves

I HAVE read Mr. Henslow's letter with interest; and of course any criticisms from him are worthy of all attention. At the same time I may observe that as yet he has only seen what may be called an abstract of an abstract. A Friday evening lecture is scarcely the occasion to work out a special statement in detail; but he is apparently criticising not even my lecture itself, but merely an abstract of it. He commences by saying that it is "self-evident" that the size of the leaf is regulated mainly by the thickness of the stem. This may be, but, so far as I am aware, the importance of this consideration had not been previously pointed out. Having, however, first disposed of my statement as "self-evident," he proceeds next to deny it altogether, and quotes cases in which the size of certain leaves have no reference to the thickness of the stem. With regard to these, however, I must observe that I was referring to leaf-areas, and as Mr. Henslow does not mention the number of leaves his illustration is incomplete. Moreover, as he was dealing merely with an abstract of what I said, he does not recognise the qualifications to which, in the lecture itself, I called attention.

As regards holly leaves, Mr. Henslow denies my statement, and questions my explanation. With reference to the fact, I should have thought there was no question. It has been stated over and over again in standard works. Sir J. D. Hooker in the "Student's Flora," for instance, says that the leaves are "spinous, adding, those on the upper branches often entire." This is entirely in accordance with my own experience. Next, as to the explanation. Mr. Henslow observes that it "seems to be attributing to the holly a very unexpected process of rationation." Surely, however, this would apply to any explanation, and in this world there must be some cause for everything. Mr. Henslow would not maintain that the pitchers of pitcher plants imply any process of rationation?

Mr. Henslow's next point is with reference to fleshy leaves, and he observes that, "Surely the usual explanation that it is this thick cuticle which prevents rapid exhalation is a better reason." A better reason for what? I was not speaking of the thickness of the cuticle but of the unusual development of the parenchymatous tissue.

Again, he questions whether "cut-up" leaves present a greater extent of surface in proportion to their mass, but surely he cannot seriously deny this.

Lastly, he doubts whether it is an advantage to water-ranunculi to have filiform leaves, because he saw a pond last summer which was dried up, and yet covered with a "carpet composed of the erect filiform branches of the cut-up leaves of *Ranunculus aquatilis*." But it does not follow that a plant placed in an abnormal situation should at once alter its habit, any more than an individual duck would lose its webbed feet because it was kept from water. Any one who will take an ordinary plant of *R. aquatilis* out of water will see at once that the leaves cannot support themselves.

I admit that my suggestions require more evidence than can be given in a single lecture, and I shall hope to develop them at greater length elsewhere; but in the mean time, though I think that Mr. Henslow's criticisms admit of answer, I am much obliged for his suggestions. JOHN LUBBOCK

Aurora at Christiania

ON the evening of March 15 an aurora appeared of unusual proportions for our part of the country. It was seen for the first time at 7.45, and then consisted of diffused and faint arches high on the northern sky. By degrees its splendor extended, and

at 8.30 it reached the zenith. In this position—from the northern horizon to zenith—the phenomenon remained almost uninterrupted all the following time. The light was rather feeble, and in the beginning the motions were insignificant. But at 10 o'clock the peculiar blazing or undulating movement that is designated by the name of *corruscation*, began to be seen, and during four hours and a half at least the whole northern half of the sky was the theatre of this uncommonly violent chase of the luminous clouds. The culmination of the aurora happened at 10.30, when on the northern sky advanced a series of splendid streamers, the inferior points of which played in red and green. This radiance was only of short duration, and later there appeared in the north only arches more or less distinct; while on the higher parts of the heavens the chasing flames incessantly continued their playing. Still, so late as 14.30 saw the flames as far as to the zenith with unimpaired violence.

I may add that on this occasion I succeeded in what I myself, as well as other friends of the aurora, have tried before in vain, viz. *to get the aurora to make impression on a photographic plate*. I exposed in all five plates; of these four (for times of exposure of 2-4 minutes) without the least trace of action, but the fifth, which was exposed during 8½ minutes, shows both a part of the horizon with a high church spire and a feeble representation of a portion of the aurora. I must, however, state that this portion in itself was but very feebly illuminated, and that at the time when the phenomenon developed the greatest power of light I was prevented from applying the camera.

The object-glass employed was: Voigtländer euroscope, No. 1; Schleussner's dry plates.

Also on the 16th, in the evening, 8.45 to 10, there appeared an aurora, but consisting essentially only of feeble fragments of arches rather low on the northern sky. The aurora has in recent times been astonishingly rare: here in Christiania, in the course of the whole winter, it has been observed on the following days:—September 14, 17, 24; October 14, 15; November 17; December 22; January 22; February 14, 16; March 12, 15, 16.

March 15 excepted, all these auroræ have been rather insignificant.

SOPHUS TROMHOLT

Christiania, March 17

"Peculiar Ice Forms"

UNDER the above caption, several correspondents of NATURE have recently described and discussed the agglutinated filamentoid ice-crystals commonly extruded from unfrozen earth under suitable conditions of moisture and temperature. B. Woodd Smith records their occurrence in the Savoyan Alps (his language implying variety of the phenomena there), and attributes them to the linear expansion incident to congelation of capillary columns of water in a thin sheet of soil resting upon rock (vol. xxxi. pp. 5-6). W. alludes to such crystals in general terms, refers to a previous notice of similar phenomena, and (erroneously) allies them genetically to hoar-frost (*ib.*, p. 29). Dr. John Rae discusses distinct (but erroneously supposed similar) phenomena at length, and argues that the several strata of crystals are remnants of successive sheets of ice or snow (*ib.*, pp. 51-2). Mr. Smith then controverts Mr. Rae's explanation, maintains his own, and refers to several earlier communications in NATURE relating to filamentoid ice-crystals (*ib.*, pp. 193-4); and subsequently he transmits a letter from John D. Paul, who has essentially repeated his own observations in the Alps (*ib.*, p. 204).

Now that it has become fashionable to revive forgotten records, it may be pointed out that these correspondents ignore the more valuable portion of the literature of their subject. Even in NATURE discussion of the fibrous ice-crystals extruded from moist earth, wet wood, &c., was epidemic fifteen years ago, and again ten years later, besides the sporadic cases of three years ago, as shown in the following bibliography:—

1870	Vol. I.	—C. Spence Bate	p. 556
,,	,,	—Mr. Pengelly	p. 627
,,	Vol. II.	—T. G. Bonney, John Langton (*sic*)	pp. 141-2
1871	Vol. III.	—T. G. Bonney, John Langton	pp. 105-7
,,	,,	—T. G. Bonney	p. 288
1880	Vol. XXI.	—Argyll	p. 274
,,	,,	—R. Meldola	p. 30
,,	,,	—Argyll	p.
,,	,,	—O. Fisher	p.
1880	Vol. XXI.	—D. Wetterhan	p.
,,	,,	—L. Bleekrode	p.
,,	,,	—S. T. Barrett	p.
,,	,,	—Wm. Le Roy Broun	p.
,,	Vol. XXII.	—John Le Conte	p.
,,	,,	—R. H.	p.
1882	Vol. XXV.	—J. F. Duthie	p.
,,	Vol. XXVI.	—H. Warth	p.

The second outbreak was practically terminated by the communications of Profs. Broun and Le Conte. The first of these gentlemen wrote from a locality in which the phenomena are readily observable, while the latter called attention to his elaborate researches of thirty years before (*Proc. Am. Ass. Adv. Sci.*, iii. 1850, p. 20-34; *Phil. Mag.*, third series, xxxvi. 1850, pp. 329-42).

More recently (February 6, 1884) Prof. Schwalbe has read before the Physical Society of Berlin the results of his observations upon filamentoid ice-crystals in the Harz. After three years' study he accepts Le Conte's views as to their genesis.

Prof. Le Conte's explanation (which is essentially identical with that subsequently offered independently by Prof. Broun) is as follows:—"Let us suppose a portion of tolerably uniformly porous and warm earth saturated with moisture, to be exposed to the influence of a cold-producing cause. The soil being an imperfect conductor of heat, only a very superficial stratum will be reduced to the freezing point. As the resistance to further expansing is less at the surface than it is at a sensible depth below, the effect of the first freezing would be to raise the apices of the capillary tubes or pores conical or pyramidal. The sudden congelation of the water, filling the conical cavities in the superior stratum, would produce a rapid and forcible expansion, which, being resisted by the unyielding walls of the cone, would not only protrude, but *project* or *detach* and *throw out* the thread-like columns of ice, in the direction of least resistance, or perpendicular to the surface. This would leave the summits of the tubes *partially empty*—a condition favourable to the development of capillary force. Under these circumstances capillary attraction would draw up warm water from below, which, undergoing congelation, would, in like manner, elongate the column of ice still higher; and thus the process would go on as long as the cold continued to operate on moistened capillaries, supplied with sufficient water from below. It will be remarked that this explanation makes the whole process of protrusion to take place in a stratum of earth of almost inappreciable thickness. It also presumes that the protruding force acts *paroxysmally*" (*Proc. Am. Ass. Adv. Sci.*, *op. cit.*, p. 20). He subsequently remarks (NATURE, *op. cit.*): "... I have to add to that given" above, "except in relation to two points, viz.: (1) that I did not sufficiently *emphasize* the importance of the fact that the water contained in the *capillary* tubes of the upper stratum of earth is cooled many degrees below the freezing temperature; and (2) that consequently the congelation will not necessarily take place *paroxysmally*."

It may be pointed out also that the great majority of the correspondents, both recent and earlier, base their explanations upon isolated observations of phenomena rare in their localities. In reality the extrusion of filamentoid ice-crystals is more common in certain localities than is indicated by Le Conte's papers and Broun's letter. Thus, in the cultivated fields of the Mississippi valley, during a cloudy day following a night of rain, with an air temperature just below freezing, the present writer has seen a thin layer of soil elevated from one to two inches over fully four-fifths of the area visible from the road throughout a day's journey. Greater length is sometimes attained by the crystals. Within a week the writer has observed along the roadsides just beyond the limits of Washington, in irregular patches and belts of straight or slightly curved filamentoid crystals, four, six, and even eight inches long. They were sometimes highest where they supported the greatest weight of earth, leaves, twigs, or pebbles upon their tops. In one case a worn quartzite pebble 1 × 1½ × 2½ inches was hoisted on a slender tuft of icy needles six or seven inches and fully two inches above the smaller neighbouring pebbles and the film of soil in which it had been imbedded.

While Le Conte's theory of the formation of the fibrous crystals extruded from moist earth or wet vegetal stems is in general way, repeated observation upon the process of development has convinced the writer that it is not paroxysmal. The ... of ...

played a very dilute solution of sodium thiosulphate (hyposulphite), which was acidified with hydrochloric or sulphuric acid, and then allowed to stand, observing from time to time the appearances when examined by transmitted light. The solution mentioned is admirably adapted for the purpose, inasmuch as the precipitation of the sulphur proceeds gradually and, according to the greater or less dilution of mixing, the completion of the reaction can be spread over a long period of time, in some of my experiments occupying more than forty-eight hours. For a while no turbidity whatever is to be observed, then a faint opalescence makes its appearance, and these exceedingly minute particles grow gradually in size, remaining, however, quite uniformly suspended for a considerable period, until a dimension is reached which causes them to settle out of the liquid. In this way I observed with unfailing regularity, and in unvarying order, though with various degrees of rapidity, or even more of the series of colours which, so far as I am aware, had not previously been noticed, or at any rate published. From minutest dots just passed successively through reddish purples to full purples, then by inevitable gradations to a fine yellow, passing, greenish yellow, to red or orange.

The solution was contained in spherical, pear-shaped flasks, or vessels with flat and parallel sides. A solution which was strong enough to give well-marked yellow, orange, and red tints, would still require for the earliest stages to be quite colourless when viewed by reflected light, the two colours were almost precisely complementary. A solution took still a sulphur tint, and was opaque to more powerful rays, a shifting before opalescence was first visible gave very feeble yellow and orange; the reds and purples, though decidedly weak, reached as far as the middle of the solution, the upper margin of the latter showing no trace of full purples, reds, and the very earliest. Solutions of the above-mentioned, and still more concentrated, [illegible] [illegible] [illegible]

"cloud-glow apparatus," by which somewhat similar results have been obtained with steam and sal-ammoniac fumes, induces me to publish my own observations, in the hope that some more competent physicist and mathematician may furnish a satisfactory theoretical elucidation. Lord Rayleigh, I find, has carefully examined the properties of the light *reflected* from an acidified solution of thiosulphate; but its action upon transmitted light appears to have escaped his attention. While Prof. Kiessling's method affords an independent confirmation of the phenomena in question, the thiosulphate solution lends itself much more readily to a study of the successive phases owing to the slow and steady nature of the action and the ease with which, by altering the strength of solution and the depth of the layer interposed, the circumstances can be adapted to the most favourable observation of any portion of the series.

J. Spear Parker

Fall of Autumnal Foliage

That the causes of the fall of autumnal foliage have been for some time removed from the *terra incognita* of the natural history of plants is clear from the fact that the threefold reason is given by Sir J. D. Hooker in so elementary a botanical work as his "Primer of Botany" (Macmillan). The cause assigned by Mr. Henslow in Nature (vol. xxxi. p. 434) will be seen, on reference to the little work mentioned, to be only one of the causes which operate in nature. I may add that I have more than once verified the third reason assigned by Sir J. D. Hooker by experiments on young and old rhododendron leaves, and on leaves of other plants, for my botany classes, and have been surprised at the great difference in the weight of mineral-ash left by equal weights of calcined leaves from the same plant, according as they were culled at the beginning or the end of the season.

Alexander Irving

Wellington College, Wokingham, March 14

[We do not think that either our correspondent or the Rev. G. Henslow has seized the point of Mr. Fraser's letter. This was not an inquiry as to the *modus operandi* by which leaves fall from the plant—a phenomenon which, as Mr. Fraser points out, ceases in India as in Europe. The process is in fact as well understood as anything in the life of the plant. What, however, Mr. Fraser drew attention to was the cause of the *autumn periodicity* of the fall in the higher latitudes as contrasted with what takes place for example in India, where the leaves, as he states, "drop off *gradually* in batches." Neither Mr. Henslow nor Mr. Irving explain why when a traveller from the south reaches Alexandria he finds that "here trees first become deciduous." Leaves fall everywhere, but why north of Alexandria *en masse* in the autumn and south of it in continuous driblets?—Ed.]

Human Hibernation

My letter on the Hibernation of the Siberian mammoth has been followed by two others, extremely interesting, but dealing, I may say exclusively, with the question of human hibernation, and the evidence offered in support of it; this raises a very important consideration, concerning which I ask leave to offer a few remarks:—The "fact," as stated by Mr. Braid, is that credible persons witnessed the burial of a man in a state of sleep or torpor, and that the same man was dug up alive some months afterwards. Why should we not believe this? The answer is not an easy one, nor can it be given in few words, but is in great measure that the same kind of almost unimpeachable testimony is to be had for any number of astounding occurrences, and that if the testimony is to be believed in one case, why should it not be accepted in all others? why are we driven to be so mistrustful? On this I will only say a few words, as your space is so limited. We know that some 5000 or 6000 years ago there existed a people—the Accadians—who, in their cuneiform writings, have left the most complete account of their daily lives and doings. We learn that these men regulated almost every act by the predictions of magicians, astrologers, or one form or another of impostors. We see, therefore, that the world was even then divided into knaves and dupes. Now this has been steadily going on ever since, and probably for indefinite ages before. The knaves having begun as such, have, for the most part, but by no means exclusively, developed into honest, or partially honest, fanatics; the dupes have greatly developed their credulity; and the stage had been reached that an individual with a sane and healthy mind when ill he escaped death, had a such difficulty as to stand a very great chance in the struggle existence. The scientific and critical revival of late years has arisen, I believe, partly because life is more secure, and education more prevalent, the virtually diseased mental condition allowed to recover itself. To apply these views to the explanation of the particular case in point above referred to as we remember that the burial was performed by men, disciples of others wholly unscrupulous, magicians, thinkers, who probably followed the same calling for ages, and acquired hereditary skill in such deceptions. Those who have witnessed as I have done, their marvellous feats—for instance, native Indian jugglers—cannot doubt but that the man buried was at all events within their power.

Messrs. Maskelyne and Cook similarly can baffle defeat the closest "scientific" examination; and it obvious but that even here, in the centre of the civilised world, the most clumsy impostors are daily bewildering befooling people who believe themselves to be the possessors highly cultivated and healthy intellects.

Athenæum Club

Bos Primigenius

In Nature, March 12 (p. 451), a specimen of the jaw of animal is referred to as having been exhibited at a meeting of Royal Physical Society of Edinburgh, followed by the remark "It is apparently the only specimen that has been found Britain." Its size is given as 18½ inches in extreme length. possess a perfect ramus of a jaw of this species, excavated Ilford, Surrey, a few years ago, which is fully 21 inches length in a straight line, and 28 inches measured along its curve. There are, I am informed, many specimens of the of *Bos primigenius* in the national collection (procured by late Sir Antonio Brady), from the same district as my specimen.

THE BRITISH ASSOCIATION AND LOCAL SOCIETIES

On behalf of the recently-appointed Corresponding Societies Committee of the British Association, the President and Secretaries are now calling the attention of Local Scientific Societies to certain Rules of the Association adopted at the meeting of the General Committee in November last. It will be remembered that during the last few years the subject of the relation of Local Scientific Societies to the British Association has received considerable attention, and that an opinion has been widely expressed that the Local Scientific Societies and the British Association might, without any considerable sacrifice of independence, usefully co-operate in facilitating the conduct of investigations into local phenomena such as are frequently undertaken by Committees of the Association.

With this purpose in view the Rules, of which we append a copy, have been prepared, and have now been formally adopted by the General Committee of the Association, and under these provisions a Corresponding Societies Committee has been appointed. To these Rules we would ask the earnest attention of the many local societies throughout the kingdom:—

"*Corresponding Societies*

"(1) Any Society is eligible to be placed on the List of Corresponding Societies of the Association which undertakes local scientific investigations, and publishes records of the results.

"(2) Applications may be made by any Society to be placed on the List of Corresponding Societies. Applications must be addressed to the Secretary on or before June 1, preceding the annual meeting, at which it is intended they should be considered, and must be accompanied by specimens of the publications of the Society on the local scientific investigations recently undertaken by the Society.

"(3) A Corresponding Societies Committee [illegible]

(3) The great eruption of Krakatoa on August 26 and 27, 1883, was accompanied by subterranean noises which were always described as resembling the rolling of cannon or of thunderstorm. The description from the Sunda Islands does not differ from that from Caïman-Brac.

(4) The subterranean sounds of the Krakatoa eruption have had an enormous intensity, and have been detected at a distance never heard of before. As is well known (*vide* NATURE, vol. xxx. p. 10), the explosions were heard over a circle of 30° radius, *i.e.* 3300 kilometres. It is indeed only the quarter of the length of the earth's diameter; if the hypothesis is true, we would have here a considerable extension of the propagation of the sound through the earth.

(5) Caïman-Brac lies very near the antipodes of Krakatoa. The exact position of Krakatoa is 105° 30′ E. long. and 6° S. lat.; Caïman-Brac, 79° 30′ W. long. and 19° 30′ N. lat. The antipodes of Krakatoa is also 4° 30′ more towards east, and 13° 30′ more towards south; it is in the middle of the United States of Colombia, on the Magdalena River, between the towns Antioquia and Tunja.

(6) The time at which the noises have been heard at Caïman-Brac corresponds sufficiently to what we know about the time of the eruption of Krakatoa. From the report of R. D. M. Verbeek (NATURE, vol. xxx. p. 10) the explosions of the volcano have been noticed in the Sunda Islands on August 26 and 27, and especially on the morning of the 27th. The noise reached its maximum at Buitenzorg on the 27th at 6.45 a.m.; at Batavia at 8.30; and at Telok-Betong at 10 o'clock. From the difference of longitude August 27, 8.30 a.m. at Batavia is the same time as August 26, 8.5 p.m. at Caïman-Brac. If we admit that the propagation of the sound through the 12,000 kilometres of the earth's diameter would take about one hour, the maximum detonations must have reached the Caïmans on August 26 at 9 p.m. Unfortunately the letter of Mr. Roulet does not give us the exact time of day at which the sounds were heard at Caïman-Brac; I have asked my correspondent to complete, if possible, his observation on that point.

I do not wait for the reply before publishing the present communication for the following reasons:—I believe it is very important to call attention without further delay to this fact, and to beg of the inhabitants of the coast and the islands of the Carribean Sea to collect all that can be remembered about these events; perhaps they heard also the noises described at the Caïmans, and they can confirm, or complete, or correct the observation given by Capt. Woodville.

In case the correlation between the noises at Caïman-Brac and the Krakatoa eruption would be ascertained, it would be a fact of uncommon interest which would equal and surpass the other astonishing phenomena to which the cataclysm of the Sunda Strait gave rise: the transmission of the atmospheric waves to the barometers of the whole earth, the propagation of the marine waves to the maregraphs of Europe and America, the crepuscular and auroral glows of the autumn of 1883, the solar corona of 1884 (which is still apparent, and can be observed every day in February and March, 1885), the abnormal polarisation of the sky (A. Cornu), &c., &c. F. A. FOREL

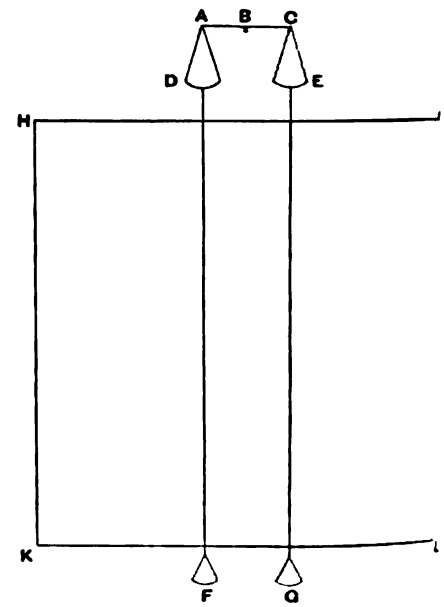
Morges, Switzerland, March 8

REMARKS ON OUR METHOD OF DETERMINING THE MEAN DENSITY OF THE EARTH

IN NATURE for March 5 (p. 408) Prof. Mayer suggests an improvement in our method of determining the mean density of the earth, from which it appears that our plan has not been properly understood. This misunderstanding, no doubt, has arisen from the incomplete description of our method given in the NATURE (Jan. 15, p. 260) of the *Proceedings* of the Berlin Physical Society. report was probably the only source of information ible to Prof. Mayer. We are led therefore to give description of our method.

Let H I K L represent a section of a cubical vessel lead, about two metres in the edge, and weighing kilos. The balance A B C is placed in the middle upper horizontal surface. It bears the scale-pans Under these scale-pans the block is bored through, and two other scale-pans, F and G, are suspended below the block, attached to the balance by means passing through these openings.

A weight in D is brought into equilibrium by weight G. The weight in D is acted upon by the earth's attraction + that of the block, and that in G by the earth attraction − that of the block. The weights in G are greater than that in D by twice the attraction of the block. The weight in D is now removed to counter-balanced by weights in E. The weight in E be less than that in F by twice the attraction of the The difference of the two weighings gives there-



times the attraction of the block. A correction is introduced for the variation in the earth's attraction to the different heights of D, E, and F, G.

In order to obtain as great a deflection of the by the method suggested by Prof. Mayer, each mercury spheres must exert the same attraction lead block. This would require spheres having about one metre. The length of the beam of the would be necessarily at least two metres. Besides mass of mercury would exert some attraction weight on the other side, and thus lessen the deflection the balance.

The method given by Prof. Mayer, except for suggested employment of mercury, is then no improvement on ours. If we should use mercury, we would struct a cubical vessel to contain it, and use it as propose to use the lead block. The advantage of mercury is, however, counterbalanced by the difficulty obtaining it in such large quantities as would necessary.

SATURN

the 6-inch reflector of Kater in 1828, if not to an earlier instrument of Short's; while their existence is now unceremoniously ignored by the gigantic refractors of Chicago, Pulkowa, and Washington; and other details might be specified, described in earlier days, but not considered or referred to now. This is certainly not what might have been expected; nor is it easy to assign the cause. Instrument, if imperfect, cannot be alleged; some minute dark markings might possibly be obliterated in telescopes which gave large spurious disks; but this plea is incompatible with the separation of extremely close stars which the modern instruments effect. Irritation cannot be supposed to affect perceptibly light of so little intensity as that of Saturn. As far as atmosphere is concerned, as in England might claim many an excuse by failure; yet Dawes and Dicky Rue and others would point to results unsurpassed elsewhere, and with no more efficient instrument than a 9½ inch mirror by With I have repeatedly seen Encke's division, while it is imperceptible with far superior means in the purer American sky. "Personal equation" might be credited with a share in the descriptions—as, for instance, when on one occasion I missed Enckehus but caught Encke's hair-line at the rare time when the reverse was attained by the well-trained eye of a friend; but this would be far from covering the whole amount of difference. It remains, therefore, to be seen whether any further advance can be made by sharper, or more widely diffused, or more persistent scrutiny. We wait for further intelligence. We have not heard how far the most remarkable investigations of Bond and his associates at Harvard have been substantiated by the same instrument in the hands of their successors. Something might be looked for at Greenwich from the ready comparison of the workmanship of Merz and Lassell. Two years have reached us from the acute research of Schiaparelli: no results from the splendid Lowell sky. A greater mass of evidence might be brought to bear upon debatable points, but, in the present state of matters, may reasonably be expected.

[illegible] information we [illegible] evidence, [illegible] We present [illegible] or may take [illegible] at [illegible] position, or brightness [illegible] Beginning of this world explain [illegible] All these [illegible] to the possible [illegible]

[illegible] authority as to our entire [illegible] object. A certain [illegible] that is before us [illegible] parliament, but [illegible] We are seldom [illegible] moon, because [illegible] and body. But [illegible] Academy, almost [illegible] Analogy, [illegible] Imagine [illegible] from [illegible] [illegible] [illegible]

to this question. They look as if they were outgrowths from the margins of the carpellary leaf, and I should probably have considered them to be so were it not for certain appearances in the ovules to which I proceed now to allude. In the free carpels, in the flowers I examined, no ovules were apparent, but only the petaloid plates just described; but in those cases where the carpels were combined into a trilocular ovary, the ovules were present on each side of the ventral suture, not indeed in a perfect condition, but in a more or less abortive state, consisting merely of a funicle and an irregular plate of cellular tissue more or less blue in colour, the only representative of the coats of the ovule, while the nucellus, so far as I could see, was entirely wanting. Still, the general appearance was that of imperfectly developed, pendulous, anatropal ovules.

Petalody, and especially phyllody, of the ovules is not a very uncommon phenomenon among Dicotyledons, and their peculiarities have been discussed at length in numerous classical treatises, to which it is not necessary here to refer. The corresponding changes in the ovules of Monocotyledons must be very much less frequent. There are none recorded in my "Vegetable Teratology," in which I endeavoured to render the bibliographical notices as complete as possible up to the time of publication, and there are none that I have hitherto been able to find in any subsequently issued publication. It is quite certain then that ovular changes must be of extremely rare occurrence in Monocotyledons. Another point remains to be mentioned—the ovules or their abortive representatives were decidedly pendulous from the ventral suture, but in the same carpel it often happened that two flat, tongue-shaped, petaloid processes projected one on each side vertically upwards from the base of the ventral suture, but quite free from it above their point of origin. These may be the representatives of ovules in spite of their different direction, for a different position of the ovules in the same carpel is by no means an uncommon circumstance, though I am not aware that it has ever been observed in *Diomella*. Naturally one is disposed to connect them with the petaloid plates projecting from the placenta above described; but unfortunately I was unable to find any intermediate condition between the petal-like plates attached to the placenta for its whole length and those which arose from the base of the carpel free throughout their entire length. It is to be hoped that this variety may have been introduced into our conservatories, where, independently of the opportunity for more complete investigation that would thus be afforded, it would be welcomed for the brilliancy of its masses of flowers.

MAXWELL T. MASTERS

MUSICAL SCALES OF VARIOUS NATIONS[1]

AT the Society of Arts yesterday, Sir F. Abel, C.B., F.R.S., Chairman of the Council, in the chair, Mr. Alexander J. Ellis, F.R.S., read a paper on "The Musical Scales of Various Nations," illustrated by playing the scales on his Dichord (a double Monochord, corrected so as to give the true intervals) and five English concertinas, specially tuned by Messrs. Lachenal, which also enabled him to play strains in some of the scales, and by various native instruments lent for the purpose by Rajah Ram Pal Singh, Mr. A. J. Hipkins, and Mons. V. Mahillon. The nations represented were chiefly those of ancient Greece, Arabia, India, Java, China, and Japan, with rapid glances at subordinate places. The relation to his former paper on the History of Musical Pitch was this, that whereas that paper gave the variations in the pitch of the European tuning note, the present endeavoured to discover the system by which different nations tuned. This was obtained when possible by theory, taking as authorities Prof. Helmholtz for ancient Greece; Prof. J. P. N. Land, of Leyden, for Arabia and Persia, and Rajah Sourindro Mohun Tagore for India. Where theory was not possible, results were obtained by measuring with his series of 100 tuning-forks the pitch of the notes produced by instruments of fixed tones (as the wood and metal bar harmonicons in Java and elsewhere), or those produced by native players on other instruments (as by Rajah Ram Pal Singh for India, the musicians of the Chinese Court of the Health Exhibition, and of the Japanese village). In obtaining these pitches Mr. Ellis was materially aided by the delicate ear of Mr. A. J. Hipkins, who most kindly cooperated with him in every way. From the pitches thus obtained, the intervals were expressed in hundredths of an equal Semitone (for brevity called cents) of which 1200 make an Octave, 702 a perfect Fifth, 498 a perfect Fourth, 386 and 316 perfect major and minor Thirds. Then these were plotted down on the movable fingerboards of the Dichord, and the scales were made audible. Occasionally forks were constructed of the pitch observed, and from them concertinas were constructed, and thus the most unusual intervals were reproduced to the ear, and their exact relation to those on a well-tuned piano rendered sensible to the eye. After rapidly exhibiting the ancient and later Greek scales, Mr. Ellis turned to Arabia, for which Prof. Land had furnished the data in his *Gamme Arabe* read before the Oriental Congress at Leyden. This showed first the Pythagorean scale, and then its modification by the lutist Zalzal, 100 years ago, whereby a fret was introduced between those for E flat, 294 cents, and E, 408 cents (supposing the open string to be C), producing the neutral Third of 355 cents, so that the scale became C 0, D 204, E neutral 355, F 498, cents, followed by the same a Fourth higher, and by a whole tone. This was the system prevalent at the time of the Crusaders, who seem to have brought it to Europe in the shape of the bagpipe, and it is still preserved in good highland bagpipes (as those of Glen and Macdonald, as was proved by taking the scale of one kindly played by Mr. C. Keene, the artist. After the time of the Crusades Arab theorists, scandalised at giving up the series of Fourths to produce the neutral Thirds and Sixths, carried on the system of Fourths to 17 notes, using 384 and 853 cents for Zalzal's 355 and 853 cents, but preserving the name. So came about the mediæval Arabic system of 17 notes to the Octave, from which 12 scales were constructed, of which Mr. Ellis was able to play 10 on one of his concertinas. But Zalzal's system did not die out, for in 1849 Eli Smith, an American Missionary at Damascus, translated a treatise by Meshâqah, a learned contemporary musician, showing that it led to the division of the Octave into 24 Quarter-tones, with the normal scale of 200, 350, 500, 700, 850, 1000, and 1200 cents, which the player was allowed, in certain cases, to increase or diminish the interval by 50 cents, or a Quarter-tone. Dr. Smith gives 95 Arabic airs in this system, of which 5 were played on a special concertina. The two important points of Arabic music were the introduction of the neutral Third and Sixth, and the variation of certain notes by a Quarter-tone, both thoroughly inharmonic.

In India the ancient scale was the same as our [illegible] major scale, with the exception of the Sixth, which was a comma sharper. Hence it had C 0, D 204, E 386, F 498, G 702, A 906, B 1088, C 1200 cents. But then the major Tones were considered to be divided into 4 degrees, the minor Tones into 3, and the Semitone into 2 degrees, and tones were depressed by 1, 2, or 3, and in one case F, raised by 2 or 3 degrees, and thus the 12 changing notes were produced, answering to the 5 chromatic notes, with 7 notes altered by 1 degree from them, equivalent to the similar process in the Arabic scale. In modern times the Scale was simplified by dividing the distance C to F on the finger-board into 9 equal parts, and from F to C (the Octave) into 13 equal parts, and then dividing the 22 degrees among the notes [illegible] (where the figure before the note indicates the number

5, 15 A very flat 736, 16 A flat 737, 17 not used, 18 A
5, 19 B very flat 952, 20 B flat 1011, 21 B 1070, 22 B
urp 1135, and then followed the Octave of the first
gree. Mr. Ellis then showed that 4 scales played to
n by Rajah Ram Pal Singh corresponded with some
the 32 scales of 7 notes formed by selections from the
ve 19 (3 of the 22 degrees not being used). There are
112 scales of 6 notes, and 160 of 5 notes, or 304 scales
all enumerated by Rajah S. M. Tagore. In addition
his the peculiarities of the 6 modes (*rágas*) and their
nerous "wives" or modelets (*rágínís*) had to be taken
consideration.

his Indian system, based on stringed instruments, is,
ever, quite different from that of any of the uncultid tribes. For instance, a wood harmonicon from
a gave the scale 0, 187, 356, 526, 673, 856, 985,
cents, where the intervals of the Fourth, Fifth, and
ave were mistuned; but the neutral Third and Sixth,
and 856, were introduced.

fter dealing with some more instruments of the same
from Singapore, Burmah, Siam, and West Africa,
Ellis proceeded to the scales which are mainly penta-
, the most perfect of which are those of Java, which
ad acquired from the band at the Aquarium in 1882,
ked by the observations of Prof. Land and others on
lar instruments in Holland. These scales are of two
ly different kinds, called Salendro and Pelog. The
of the first seems to be the division of the Octave
five equal parts, giving the scale 0, 240, 480, 720, 960
cents., so that there is a flat Fourth, sharp Fifth, and
st perfect natural Seventh (960 for 969 cents.). By
ng pentatonic Scotch airs on a concertina thus
d, Mr. Ellis showed that the scale gave perfectly
gnisable results, and he then played some Javese
reported by Raffles. In this scale no interval
ween successive notes was so small as a whole Tone,
large as a minor Third, but approached a neutral
cents, which is constantly accepted as one or the
r almost indifferently.

he second or Pelog scales have also five notes, but
are selected from a fund of 7, which (being numbered
VII.) have the following intervals from the lowest
nts:—I 0, II 137, III 446, IV 575, V 687, VI 820,
1098, I 1200. From these the annexed scales were

[illegible] played short strains (not native) to show the effect of these scales on ears.

[illegible] the Javanese [illegible] and the [illegible] of the Chinese [illegible] Court, to take down the pitches of the notes played by [illegible] the Javanese [illegible] Sunda, [illegible] the Javanese [illegible] the Javanese [illegible] the Javanese [illegible] diverse. Probably [illegible] the holes, 1 and 2 were [illegible] together, but the scales [illegible] 2, 3, 4, 5 had all scales of [illegible] usual to leave out two notes and [illegible] pentatonic scales only were played to them. No. 1 also were tuned in their presence. No. 1 was suggested to follow what is given as the scale in Williams's Middle Kingdom, but must have been badly tuned. The following gives the transcription of the Chinese names followed by the cents in the interval from the lowest note. The notes marked * were omitted when only five notes were used:—*Ho* 0, *sze* 169, **shang* 274, *chang* 491, *kung* 661, *pien kung* 878, **fan* 996, *liu* 1200, which may possibly represent the scale of B flat major, begun on its second note, thus C 0, D 182, **E flat 294, F 498, G 680, A 884, **B flat 996, C 1200. Also the scale played on No. 6, if begun on its Fifth, seemed to be the same. This is the only instance Mr. Ellis met with where two scales were approximately the same. No. 6 has no frets, and hence any intervals were practicable upon it. None of the instruments used equal temperament.

The principal scales of Japan are pentatonic, but they have a means of sharpening notes on the *Koto* by pressure on the strings, thus producing more notes. The "classical" music came from China. The "popular" seems to be indigenous. In this case, in the *hirajoshi* tuning of the *Koto* (the principal national instrument), both Mr. Ellis's authorities (Mr. S. Isawa, Director of the Institute of Music at Tokio, Japan, and a Japanese at present studying physics in Europe) agree that the intention is given the note of the 1st and 5th strings in unison, to tune the 2nd a Fifth below it, and the 3rd a Fourth below it. As to the 4th they disagree. Mr. Isawa thinks it was meant a major Third below, the other thinks his countrymen [illegible] know a major Third, but only tune the 4th string to "a sort of instinct" as "a sort of" Semitone [illegible] in which case the interval between the 3rd and 4th will also be "a sort of" major Third, and the Fifth from the 3rd to the 5th string, will be approximately divided into a Semitone and a major Third, which is [illegible] enough, the oldest Greek tetrachord of [illegible] tuned by a similar "instinct." Then the Fourth from the 5th to the 7th string, would be similarly divided by the 6th string. Hence, taking the 1st and 5th strings as E, we have 1 E, 2 A, 3 F, 4 C, 5 E, 6 F, a approximately. Mr. Buhicrosan, of the "Japanese Village," Knightsbridge, kindly allowed Mr. Hipkins and Mr. Ellis to take the method of tuning [illegible] from one of his female musicians and her [illegible] the number of cents in the [illegible] the following was the result:

year 1887. The Government has proposed, and the Chambers have adopted a law having for its object the preservation of fish and their restoration to the rivers. The main obstacle to this end is the pollution of the waters of small unnavigable streams by solid and liquid matter poured into them by various industries, which render them unfit for the breeding and existence of fish. The Academy, therefore, calls on science to aid the public authorities. One of its members has placed at its disposal the sum of three thousand francs, which it has decided to spend in giving a prize for a thorough study of the following questions, at once biological and chemical:—(1) What are the special substances in our principal industries which, when mingled with the water of small streams, render them incompatible with the existence of fish and unfit for the consumption of man and beast? (2) Investigation and indication of practical measures for purifying water as it leaves manufactories, so as to render it innocuous to fish without interfering with the industry, combining the expedients offered by decanting basins, filtering and chemical agents. (3) Separate experiments on the substances which in each special industry kill fish, and on the degree of resistance which each species of edible fish offers to this destruction. (4) A list of the rivers in Belgium which are actually depopulated by this state of things, with an indication of the special industries in these rivers, and a list of the edible fish which inhabited them before the establishment of the factories. If a memoir is judged satisfactory for the solution of the two first points, a prize of two thousand francs will be given, even though the two latter questions are untouched. Papers should be legibly written, and should be addressed to M. Liagre, Perpetual Secretary, au Palais des Académies, Brussells, before October 1, 1887. Quotations are to be made with great exactness, and authors should therefore mention the edition and page of works cited. A motto must be selected, and the names inclosed in a separate sealed envelope, with the motto superscribed. The papers sent in will remain in the archives of the Academy.

A RECENT issue of the *Peking Gazette* contains a report from the outgoing Viceroy of Fukhien stating that he had handed over the insignia of office to his successor, including *inter alia* the seal, the imperial death warrant, banners and tablets, and the conch-shell best used by the Throne. The latter has a curious use. A conch-shell with a whorl turning to the right is supposed when blown to have the effect of stilling the waves (from the excruciating nature of the sound?), and is hence often bestowed by the Emperor upon high officers whose duties compel them to take voyages by sea. The Viceroy of Fukhien probably possesses one of these shells in virtue of his jurisdiction over Formosa, to which periodical visits of inspection are supposed to be paid.

UNDER the title "A Prophetic Almanac a Hundred Years ago," *Science et Nature* describes, with illustrations, portion of one of a series of almanacs issued between 1789 and 1799, which has recently been presented to the Paris Bureau of Meteorology. The collection was made at the time by Guénenu Montbeillard, the colleague of Buffon, and the author of the section on birds in the latter's natural history. Montbeillard was also a meteorologist, and his observations, made at his chateau at Semur in Côte-d'Or, can be employed to check the prophecies made in the *Almanach fidèle* published annually at Troyes, "par les soins du sieur Maribas, grand astrologue et mathématicien." Selecting the page of the almanac for the month of March, 1785 (precisely a century ago), we find in the last column, in ordinary language, general predictions for the four quarters of the month. For example: "New moon on the 10th, at 10h, 38m. in the evening, in the sign Pisces. The weather will be fine, and the winds very troublesome." Next to this come four columns, filled with cabalistic signs and occupying the middle of the page. The last of these gives for each day the position of the moon in one of the zodiacal signs. The first of the four [illegible] by a [illegible] a triangle whether the day is a festival or a working day. In the second column the nature of the weather which may be expected is marked by a succession of signs, the key to which is given in the first page, while the third, by a similar series of signs, indicates the nature of the operations for which the day in question is particularly favourable. Thus Sieur Maribas advises his clients that March 10th, 11th, and 28th, 1785, are favourable for hair-cutting; the 12th, 13th, and 27th for paring the nails; the 2nd, 14th, and 21st for blood-letting; less than six only one day, March 4, on which pills should be taken, while it would be unwise to wean infants on any day but the 19th. For wood-cutting, the 9th, 15th, or 16th should have been selected, and so on. The philosopher's weather predictions for the month appear to have been falsified in almost every instance. He foretold rain for seven days and snow for two; in fact it rained very slightly on three days, none of which were mentioned by him, and did not snow on his days at all. In temperature he was as bad, for the day which he foretold would be warm was the coldest of the whole year. Besides, "the various changes of the air for each day produced by the stars on our horizon," Sieur Maribas promises in his title-page, "several pretty sayings suitable for exhilarating and diverting curious and enlightened minds." Among these meteorological *gentillesses* are the following:—Women are cured of laziness by vanity or by love; to know a woman well, it is necessary to contradict her; Nothing grows old so soon as a benefit. The "grand astrologer and mathematician" evidently intended his "pretty sayings" chiefly for those of a melancholic turn of mind.

WE have received the *Proceedings* of the Holmesdale Natural History Club for the years 1881, 1882, and 1883. This club has its home at Reigate, and its papers, though mainly concerned with south and central Surrey, range over a great variety of natural history subjects. Among the principal papers in the number (which, it should be remarked, would be much improved by an index, or classified list of the papers) are:—The potato disease, by Mr. Gill; the hairs of plants as concerned in the supply of water and nourishment, by Dr. Bossey; ornithology in Wray Park, by Mr. Crosfield; the *Sérolegna ferax* (the fungoid water fish parasite), by Mr. Boyle; the habits of the wall-eyed crustacea of the British Islands, by Mr. Lovett; and the marine life of the Reigate district, by Mr. Gilbert. All the excellent work of the Club appears to be done with an expenditure of from 30*l.* to 40*l.* per annum.

WE are asked to state that in the report of Sir William Thomson's Baltimore lectures, p. 296, in line 13 from the top of the page, and in the left hand members of equations (19) and (21), for "ω" and "ω_1" read "ϖ" and "ϖ_1" respectively.

THE additions to the Zoological Society's Gardens during the past week include a Malbrouck Monkey (*Cercopithecus cynosuros*) from South Africa, presented by Mr. W. E. Cliff; a Green Monkey (*Cercopithecus griseo-viridis*) from South Africa, presented by Mr. W. Ockey; a Pine Marten (*Mustela martes*) from Ireland, presented by Mr. Frank Sharp; a Bay-bellied Viverra (*Munia niviceps*) from Java, two St. Helena Sooty-Eaters (*Phaethagra fuliginosa*), a Grey-necked Serin Finch (*Serinus canicollis*), a Brown Canary Finch (*Serinus fatuus*), two —— Finch (*Serinus* ——) from South Africa, presented by Mr. J. Abraham, two Pheasants (*Phasianus colchicus*), British, deposited, a Stein-bok (*Nanotragus tragulus* ♀), four Wattled Starlings (*Dilophus carunculatus* ♂ ♂ ♀ ♀), two White-throated Sooty Eaters (*Crithagra albogularis* ♂ ♀), two Striated Colys (*Colius striatus*) from South Africa, two Brazilian Tanagers (*Euphonia violacea*), two Green-headed Tanagers (*Calliste procera*) from Brazil, purchased

By relief maps and the convenience and accuracy of maps on flat surfaces. The Correspondent states that this new method rapidly reproduces, by a mechanical process, plane maps with the curves and altitudes in relief, so represented as to correspond absolutely with the elevations established by accurate observations. These maps are drawn on paper, which may be described as plain. They are not, however, put out of shape even by being soaked upon. Yet they may be rolled up and placed in the narrowest case, or that they are very portable and light. They are not injured by water. The Correspondent soaked one of them for forty-eight hours in water, and, on taking it out, all the part which was in relief—that is all the part submitted to the mechanical process—remained absolutely intact. The relief, the Correspondent states, is produced on them in such a manner that at a single glance one can take in the whole topography of a district, its declivities and heights, its water-courses, and all the precise characters of the country in which military operations have to be carried on. Of course relief maps are well known and plentiful. The drawback to those which include large areas is that the altitudinal scale has to be greatly exaggerated, thick as it commonly is. Switzerland is a solid block of limited area, 50 inches, not only in plaster, but also in paper-mâché, the horizontal and altitudinal scales of which are the same. These new maps, however, seem to possess many advantages over either plaster or paper-mâché, and we should like to know how large are the areas which are contained on them. We are also curious to learn the charges of these, and whether contracting is met to some extent intelligently.

In the *Mitth. Ausgaben* of the Vienna Geographical Society for February (Bd. xxviii. No. 2.) Prof. Hellwald describes the Lake-dwellings in the Philippine Islands at the time of the Spanish Conquest. These were of two kinds: Moharnahechan, rangahanes, which were the larger and more important, the palaces of which were found in the feudal system ; and a wooden village each, in which the Government was. On the whole, a complicated system of society. The latter is described at considerable length and is exceedingly interesting. Herr Heller completes his paper on the Indo-Dorians, which Baron Kaulbars translates from the Russ for the second number (vol. v.) of Petermann's Central Asia. The Russian, we are glad to observe, will be continued. Dr. Supan, of Gotha, writes with reference to the Congress of German Geographers, which is to meet at Berlin on April 21, and will be followed by a meeting of the Central European Commission, under the presidency of the Austrian General Von Sterneck. Dr. Supan also announces that the Geographical Society of Leipzig has just now completed the fifth year of its existence. At the meeting on February 24, Dr. E. Metzner lectured on Mt. [illegible] and Attempts and Plans for the Exploration of the Interior of Africa. Dr. Supan also announces that the Geographical Society of Leipzig has just now completed the fifth year of its existence. At the meeting on February 24, Dr. E. Metzner lectured on Mt. [illegible] and Attempts and Plans for the Exploration of the Interior of Africa.

THE ELECTRICAL EXHIBITION AT PHILADELPHIA

[illegible]

to the loss of the *Doterel* on April 26, 1881, while at anchor off Sandy Point, by an explosion, or rather by two distinct explosions following each other in very rapid succession, which caused the death of eight officers and 135 men, there being only twelve survivors of the crew. The inquiry by court-martial into the catastrophe had led to the conclusion that the primary cause of the destruction of that vessel was an explosion of gas in the coal-bunkers, caused by disengagement of fire-damp from the coal with which these were in part filled. Its distribution through the air in the bunkers and in air-spaces adjoining the ship's magazine was believed to have taken place to such an extent as to produce a violently explosive mixture, and that this had become accidentally inflamed, causing a destructive explosion, which was followed within half a minute by the much more violent explosion of the ship's magazine, containing four or five tons of powder, to which the flame from the exploding gas-mixture had penetrated.

The circumstances elicited by the inquiry, coupled with the information relating to explosions known to have occurred in coal-laden ships which had been collected by a Royal Commission in 1876 (of which the lecturer was a member), combined to lend a considerable amount of probability to the view adopted by the court-martial in explanation of an accident for which there appeared to be no other reasonable mode of accounting.

The conclusion arrived at led to the appointment of a committee under the presidency of Admiral Luard (of which Prof. Warington Smyth and the lecturer were members) to inquire into the probabilities of coal-gas being evolved, and of an explosive gas-mixture accumulating in consequence in the coal-bunkers of ships of war, and into the possible extent and nature of damage which might be inflicted upon ships of war by explosions due to the ignition of such accumulations. The committee were also instructed, in the event of their finding that H.M.'s ships were liable to exposure to danger from such causes, to consider and devise the means best suited for preventing dangerous accumulations of gas in the coal-bunkers which are distributed over the various parts of the ship in the different classes of vessels composing the Royal Navy.

The committee instituted a very careful inquiry, and a series of experimental investigations, including the firing of explosive gas-mixtures, in large wrought-iron tanks in the first instance, and afterwards in one of the large bunkers, empty of coal, in an old m an-of-war, which afforded some comparison with the condition, as regards the relative strength or powers of resistance of the surroundings, and with the position, relatively to the ship's magazine, of the particular bunker in the *Doterel* in which it was thought the explosion might have originated. The results of these experiments could not be said to do more than lend some amount of support to the belief that effects of the nature of those ascribed to the first explosion in the *Doterel* might have been produced by the ignition of a powerfully explosive gas-mixture, contained in the middle or athwart-ship's bunker of the ship. The committee's experimental investigations for ascertaining the best general method of securing the efficient ventilation of the coal-bunkers in different classes of men-of-war was, however, of considerable advantage in leading to the general adoption of arrangements in H.M.'s ships whereby the possible accumulation in the bunkers of gas which may be liable to be occluded from coal after its introduction into them is effectually prevented, and the occurrence of the kind of accidents guarded against, of which there are several on record, due to the ignition of explosive mixtures which have been produced in coal-bunkers.

Although the inquiry instituted by the court-martial in August, 1881, into the loss of the *Doterel* was apparently very exhaustive, some significant facts connected with the existence of a supply of xerotine siccative in the ship, which appear to have had a direct bearing upon the occurrence of the disaster, only came to light accidentally in January, 1882. A cadet formerly on the *Doterel*, but then employed in the *Indus*, recognised, while some painting was being done in that ship, a peculiar odour (as he called it, "the old smell") which he had noticed in the lower part of the *Doterel* the night before the explosion; on inquiry as to the material which gave rise to it, he learned that it was due to some of the same material, xerotine siccative, that had caused the explosion in the *Triumph*. Upon this being communicated to the authorities, an official inquiry was directed to be held, and it was then elicited that the very offensive smell due to the crude petroleum spirit of which this xerotine siccative mainly consisted, had been observed not only by this man (who in his evidence before the court-martial had not alluded to the circumstance), but also by several other of the *Doterel*, between decks, the night before the explosion, and on the following day, a search was made for the cause of the odour, and that a jar containing originally about a gallon of the fluid, which was kept in a space at the bottom of the bunkers together with heavy stores of various kinds, was found to have been cracked, the principal portion of its contents having leaked out into the bottom of the ship. The cracked jar was hauled up to the lower deck with the siccative still leaking from it, and orders were given to throw it overboard on account of the bad smell which it emitted; this was done within a very few minutes after the jar had been removed, and the first explosion occurred almost directly afterwards. Instructions had been given to clear up the leakage from the jar after the hatch of the manhole had been left off a little time, and it appeared that a lubricant had been given to the man who handed the jar up out of the small store-hold described by that name. There appears very little room for doubt that an explosive mixture of the vaporised air had not only been formed in the particular space where the jar was kept, but that it had also extended through the bunkers at the bottom of the ship towards and underneath the powder magazine, so that even the air in the latter may have been in a explosive condition, as many hours had elapsed between the time when the smell of the petroleum spirit-vapour was first noticed and when the first explosion occurred.

The special committee which had inquired into the question of the occurrence of a violent gas explosion in the coal-bunkers of the *Doterel* was directed to institute experiments with a view of ascertaining whether the vapour evolved by this xerotine siccative would, in the circumstances indicated by the court-martial inquiry, have furnished an explosive gas-mixture possessing sufficient power to have produced the effects resulting from the first explosion on the *Doterel*, and to have exploded the powder in the magazine. A preliminary experiment showed that when a small quantity of the liquid was spilled at one extremity of a wooden channel 7 feet long and 2·5 inches by 3 inches in section, its vapour had diffused itself in the space of three minutes throughout the channel to such an extent that, on a light being applied at one end, the flame travelled along very rapidly to the other end, igniting a heap of gunpowder which had been placed there. Some of the liquid was also spilled upon the bottom of a very large sheet-iron tank, and after this had remained closed for about twenty-four hours, being exposed on all sides to the open air of an autumn night, and therefore not under conditions nearly so favourable to evaporation as those obtaining in the hold of a ship, the application of flame produced an explosion of great violence as to tear open the tank. Experiments were also made with the liquid in an old man-of-war, under conditions generally similar to those which existed in the *Doterel*, and precisely similar effects were obtained of a nature to warrant the conclusion that the first explosion in the *Doterel* might have been the result of ignition of an explosive mixture of the air in the coal-bunkers at the bottom of the ship, with spirit vapour furnished by the liquid which had leaked out of the jar.

It is very instructive, as indicating the manner in which certain liquids of this class may, if their nature be unsuspected, be the causes of grave disasters, to note that, while stringent regulations apply, and are strictly enforced, in our men-of-war in connection with the storage and treatment of explosives and inflammable bodies carried in the ship, the introduction into the ship of this highly volatile liquid, and its supply to ships in considerable quantities, was speedily followed by two most calamitous accidents because the material was only known under the designation of a name affording no indication of its character. Its introduction through whose hands it had passed, the makers of the petroleum having, in a reprehensible manner which cannot be too severely stigmatised as criminal, withheld the information which probably would have, at the outset, acted as a prohibition of the adoption of this material by the Admiralty for use in the ships, or which would, at any rate, have led to the adoption of such special precautions in dealing with this material.

Although not initiated, nor attended, by any explosion, the accident which in December, 1875, caused the loss, by the death of several of the boys by drowning, affords a striking illustration of the facility with which, by needlessness, or inattention to obvious precautions, accidents may be brought about in the use as an illuminating agent of mineral oil of petroleum, even where these are of such low volatility, or high [illegible]

nt," as to entitle them to be considered as safe, under all inary conditions, as vegetable or animal oils. The evidence ited at the coroner's inquest showed that one of the boys of *Goliath*, whose duty it was, at the time, to trim the lamps used he ship, to place them in position and remove and extinguish n in the morning, and to whom this work had been but recently ted, let fall a lamp which, after having lowered the flame, had carried from its assigned position into the lamp- or ming-room, and which he could hold no longer on account its heated state. The heated oil was scattered upon the r, and was apparently at once inflamed by the burning wick the lamp; the floor of the room was, it appears, much in- gnated with oil which had been let drop from time to time ads employed upon the work of lamp-trimming; hence the e attacked the apartment generally with considerable idity, and a wind blowing at the time caused the fire to ead through the vessel so very quickly as to compel many of se composing the crew to jump overboard, and to render the ue of the boys from burning or drowning a difficult matter. e occurrence of this accident was made the occasion, in some the public papers, to decry petroleum oil as a dangerous minating agent, although it was proved that the particular used at the time when the fire occurred had so unusually high shing-point that the consequent inferiority of its burning lity had been made the subject of complaint. This low tility of the oil has been occasionally regarded as one very ortant element of safety in reference to its employment in ps, but the lecturer will presently have to refer to circum- ces which do not substantiate this view. At any rate, rever, although the heated oil which was spilled on to floor from the lamp was in a condition favourable to immc e ignition by the burning wick, it is not at all likely that the would have extended almost at once with uncontrollable ence, especially in face of the excellent discipline and ngements in case of fire which were shown to have existed he *Goliath*, if the scrupulous cleanliness and care had been rved which were essential in a room where lamp filling and ming were regularly carried out, and where it was necessary ep some supply of oil for current consumption. Instead of the floor, and probably therefore other parts of the room, ear to have been in a condition most favourable to the rapid agation of the flame; moreover, the evidence as to proper having been taken to keep the supply of oil required for ent use in such a way as to guard against its being accident- applied, or to impress the boys employed upon the work the great importance of care and cleanliness, was by no ns satisfactory, and there can be little doubt that this casu- lty has to be classed among the numerous accidents of a ly avertible kind which have contributed to lead the public orm an exaggerated estimate of the dangerous character of oleum oil as an illuminant.

he employment of liquid hydrocarbons as competitors with nal and vegetable oils in lamps for domestic use is of com- tively recent origin, although petroleum or mineral naphtha s crude or native conditions was used at a very early date in ia and in Japan, in lamps of primitive construction, while ely it was similarly employed about a century ago.

he application of the most volatile products of coal distilla- to illuminating purposes in a crude way appears to have inated, so far as Great Britain is concerned, with the work- of a patent taken out by Lord Dundonald in 1781, for the illation of coal, not with a view to producing gas, but for the uction of naphtha, brown or heavy oil, and tar.

1820, or about the time when gas-lighting was being estab- d in London, his successors sold coal-naphtha in the metro- s for illuminating purposes; but the first really successful duction of naphtha as an illuminating agent was made by Astley shortly afterwards, through the agency of the ar- d Founders' blast-lamp, which came into use for workshops yards in factories, and of the naphtha lamp of Read Holli- of Huddersfield, with which we are well acquainted to this e, although it never became a success for internal illumina- of houses, it still continues in extensive use almost in its nal form, by itinerant salesmen and showmen.

the Founders' lamp a current of air, artificially established, made to impinge upon the flame and thus to greatly assist combustion of the crude heavy oil used in it.

the Holliday naphtha lamp the spirit finds its way slowly the reservoir through a capillary tube to a small chamber placed at a lower level, which has a number of circumferential perforations, and is in fact at the same time the burner of the lamp and the vapour producer which furnishes the continuous supply of illuminant, the liquid supplied to the chamber being vaporised by the heat of the jets of flame which are fed by its production.

Between 1850 and 1850 the knowledge of the production not only of oils but also of paraffin by the distillation of coal or shale became considerably developed by Reichenbach, Christi- son, Mitscherlich, Knue, du Buisson, and others, and the prac- tical success attained by the latter was soon eclipsed by that of Mr. James Young, who, after establishing oil distillation at Alfreton from the Derbyshire petroleum, began to distil oils from the Bathgate mineral in 1850, and soon developed this industry to a remarkable extent.

The first lamps for burning liquid hydrocarbon which com- peted for domestic use, in this country, with the superior kinds of lamps, introduced after 1835, in which animal or vegetable oils were burned (solar lamps and moderator lamps), were the so-called camphine lamps (known as the Vesta and Paragon lamps) in which carefully rectified oil of turpentine was used. They gave a brilliant light, but soon acquired an evil reputation as being dangerous, and liable, upon the least provocation, especially if exposed to slight draughts, to fill the air with adhesive soot-flakes.

After a time Messrs. George Miller and Co., of Glasgow (who held for a time the concession of the products manufactured by Mr. Young) tried with some amount of success to use the lighter products from the boghead mineral in the camphine lamp, but the chief aim of Mr. Young appears to have been to produce the heavier oil suitable for lubricating purposes, the light oil or naphtha meeting with an indifferent demand as a solvent, in competition with coal-tar naphtha, in the manufacture of india- rubber goods. He, however, himself used the mineral oil pro- duced at Alfreton in Argand lamps in the earliest days of his operations; a small sale of the Bathgate oil took place about 1852-53 for use in Argand lamps, and the earliest description of lamp employed in Germany, where the utilisation of mineral oil as a domestic illuminant was first developed, appears to have been of the Argand type.

In 1853 a demand sprang up for the lighter paraffin oils in Germany. For three or four years previously a burning oil was distilled from schist or brown coal at Hamburg by a Frenchman named Noblée, who gave it the name of *photogene*. The exist- ence in Glasgow of a considerable supply of the oils hereto known to a German agent, and after they had been exported from Glasgow to Hamburg for a considerable time it was found that the chief purchaser was Mr. C. H. Stobwasser, of Berlin, who appears to have originated the really successful employment of mineral oils in lamps for domestic use, and to have been the first to bring out the *flat*-wick burners for these oils. After a time Messrs. Young discovered the destination of their oil, and, having brought over a number of German lamps, for which a ready sale was found, commenced the lamp manufacture upon a large scale, and rapidly developed the trade in mineral (or paraffin) oil for burning purposes, which attained to great im- portance some time before the American petroleum oils entered the market. In 1859 a firm in Edinburgh supplied Young's company with nearly a quarter of a million of burners for lamps, and it was not until 1859 that the foundation of the United States' petroleum industry was laid by Col. G. L. Drake, who first struck oil (in Pennsylvania) at a depth of 71 feet, obtaining at once a supply of 1000 gallons per day. The lamps first used in America were probably of German make, but it need hardly be said that the lamp manufacture was speedily developed to a gigantic extent in that country. Some of the earliest lamps for burning mineral oil in dwellings which were produced in Ger- many and in Scotland, possess considerable interest as ingenious devices for promoting the perfect and steady combustion of the oil, and as attempts to dispense with the necessity of the chimney for the production of a steady light. In one of these a small lamp was introduced into the base or stand of the lamp proper, and a tube passed from over this little lamp, through the oil reservoir into the burner, so as to supply the latter with heated air. In another, a small fan or blower, with simple clockwork attached, to keep it in rapid motion, is placed in the stand, and supplies the flame with a rapid current of air. Among other workers at the perfection of mineral oil lamps was the late Dr. Angus Smith, who produced a double-wick lampsome years before the beautiful duplex-lamps were first manufactured by Messrs

Hinks. Some of the more recent American lamps exhibit decided improvements in the details of construction of the oil reservoirs, the wick-holders and elevators, the arrangement for extinguishing the lamps, &c.

It does not come within the province of this discourse to deal with the marvellous development of the petroleum industry in America, where the region of Western Pennsylvania now furnishes about 70,000 barrels of oil per day, having up to January 1, 1884, yielded a total of 250,000,000 barrels. Nor would it be relevant to enter upon the equally interesting topic of the recent extraordinary progress of the same industry in the Caucasus, which is chiefly due to Messrs. Nobel Brothers, further than to refer to the fact that the Baku petroleum lamp oil, which supplies the entire wants of Russia, and is gradually obtaining a footing in Germany, and even here, appears, notwithstanding its comparatively high specific gravity, to be adapted for use in mineral oil lamps of the ordinary construction. This seems to be partly owing to the comparatively small proportion of lamp oil that is extracted from the crude Baku petroleum, in consequence of which the variety of hydrocarbons composing that product of distillation which is used for illuminating purposes, presents a narrower range than is the case in the ordinary American petroleum foil of commerce. It has also been established by careful observations which Beilstein has instituted, that some American oil which is specifically lighter than the Baku oil is not so readily carried up to the flame as the latter, by the capillary action of the wick. Mr. Boverton Redwood has carried out some instructive experiments, employing different kinds of wick as siphons, and measuring the quantity of different descriptions of oil drawn over in corresponding periods of time by the different wicks. These showed that the Baku kerosine was drawn over with decidedly greater rapidity than samples of American petroleum of ordinary quality, but that, on the other hand, a sample of American kerosine of the highest quality exhibited a corresponding superiority over the Baku oil experimented with. The nature and behaviour of the wick plays a most important part in determining the efficiency and also the safety of a mineral oil or petroleum lamp, as will be presently pointed out.

Ever since paraffin or petroleum oils, which may be included under the general designation of mineral oils, first assumed importance as illuminating agents, accidents connected with their use have continued to claim prominence among those casualties of a domestic character which tend to cast suspicion on the safety of the material dealt with, or of the method of employing it, under the ordinary conditions fulfilled by its careful use.

The employment as an illuminant of the most volatile portions of petroleum which are classed as spirit or naphtha, has been chiefly limited to the wickless Holliday lamp, in which a small continuous supply to a chamber heated by the lamp flame which surrounds it, furnishes the vapour which maintains that flame, and to the small so-called sponge lamps or benzoline lamps, of which the body is filled with fragments of sponge, and which is intended to be charged only with as much spirit as the sponge will hold thoroughly absorbed; the small flame at the top of the wick-tube being fed by the gradual abstraction of the liquid from the soaked sponge, by the wick of sponge or asbestos which fills the tube. An ingenious application of naphtha as an illuminant consists in filling a reservoir with sponge fragments kept soaked with the spirit, the vapour of which descends by its own gravity through a narrow tube at the base of the reservoir, and issues from a fish-tail burner under sufficient pressure to produce a steady flame for some time.

(To be continued.)

SOCIETIES AND ACADEMIES

LONDON

Mathematical Society, March 12.—J. W. L. Glaisher, F.R.S., President, in the chair.—Messrs. Philip Magnus and R. Lachlan were elected Members.—Mr. J. J. Walker, F.R.S., made a second communication on a method in the analysis of plane curves.—Mrs. Bryant, D.Sc., read a paper on the geometrical form of perfectly regular cell-structure. "Investigation of the properties of the rhombic dodecahedron supplies the clue to the solution of two interesting questions, which are the essential, because the pure geometrical, constituent of several questions as to actual forms in physical nature, such as the geometrical structure of compact tissues on the one hand, and the geometrical form of the honeycomb cells on the other hand. The first question is as follows:—If space were filled with spheres, and this spaceful of spheres were then crushed together symmetrically till the whole became a solid mass, what shape would each sphere ultimately assume? Since owing to the number of spheres that can be placed round one sphere, in contact with it and with one another, it is evident that each of their ultimate solids would be dodecahedral in shape. The second question is the counterpart of the first:—If space were filled with a homogeneous solid, in which equally efficient cases of excavation were distributed uniformly, what would be the ultimate form of the cells excavated, it being supposed the when the excavators cease their work the walls of the cells are uniform in thickness? The answer to the first question is manifestly the answer to the second question also." After a geometrical discussion the author says:—"We should expect to find this dodecahedral shape in nature wherever originally spherical cells have been uniformly pressed together in a complete manner. The condition is probably seldom fulfilled, and examples are therefore difficult to find. We may look for their fulfilment, however, in the centre of a mass of soap-bubbles." The paper then considers the case of the honeycomb cells, with the conclusion: "The above explanation tends, however, to show that the bees need not be credited with any economical instinct to account for their work, but only with those simpler instincts, which enable them to carry out a joint work with perfect regularity and economy, which simpler instincts, while sufficiently remarkable, are kept within the limits of credibility."—Mrs. Bryant illustrated her remarks with several models of the cube and the rhombic dodecahedron.—Mr. Kempe, F.R.S., and the President (who said that he had some few years since considered the matter from another point of view) made some interesting remarks in connection with the subject.—Prof. Sylvester, F.R.S., gave an account of a paper on the constant quadratic function of the inverse co-ordinates of $n + 1$ points in space of n dimensions, and Prof. Cayley, F.R.S., and Prof. Hart spoke on the same subject. As the hour was late Mr. Tucker (hon. sec.) only communicated the titles of papers by Prof. K. Pearson (on the flexure of beams); Rev. F. C. Simmons (two elementary proofs of the contact of the "N.P." circle of a plane triangle with the inscribed and ascribed circles, together with a proof of the common tangents); and by himself (two other proofs of the first part of Mr. Simmons's communication).

Linnean Society, March 5.—Sir J. Lubbock, Bart., President, in the chair.—Messrs. Jas. Epps, Jas. Groves and Wm. Ransom were elected Fellows of the Society.—Mr. E. M. Holmes exhibited a number of new species of British algæ, viz. thirteen from the south coast of England, and six obtained from Berwick-on-Tweed and Fifeshire. He also called attention to examples of the leaves of *Eucalyptus Staigeriana*, which are remarkable for their fragrant odour, resembling that of verbena, due to a volatile oil which is stated by Mr. Bailey, the Government botanist at Brisbane, to be likely to form an article of commerce in the future. Mr. Holmes also showed a set of plant fabrics woven from the leaves of the Talifat palm.—Mr. W. Brockbank exhibited a specimen of *Leucojum carpathicum*, a variety of *L. vernum*, differing from the type by having the flowers tipped with yellow instead of green. The *L. carpathicum* is said to be seldom met with in English nurseries.—Mr. C. B. Plowright showed and made remarks on a Ranunculus infected with spores of *Uredo ranunculacearum*.—Mr. F. Wetherell exhibited some microscopic sections of the "Better Bed" coal-seam of Yorkshire and of the "Splint" coal from Whitehill Colliery near Edinburgh. He mentioned that Prof. Huxley had drawn attention to the former as containing in quantity spores and pollen of plants allied to the recent club mosses. Mr. Wetherell averred that these were only found in numbers in the lowest three inches of the coal-bed, but very sparsely in the higher portion of the seam. In the Edinburgh splint coal only four inches of the basal and but a part of the upper layer contained spores. Macrospores and microspores were present in both the Yorkshire and, judging from these, he regarded them as belonging to plants resembling or allied to the recent genera *Selaginella* and *Isoëtes*. Mr. W. Carruthers replied, and dissented from Mr. Wetherell's view.—Dr. F. Day read a paper on the rearing, growth, and breeding of salmon in fresh water in Great Britain. He referred to the statements and opinions of the older authorities, and more especially dwelt more at length on the more recent experiments of Mr. James Maitland at Howietoun. In December, 1880, Mr. [illegible]

obtained salmon eggs and milt from fish captured in the Teith, and which ova hatched in March, 1881. In July, 1883, it was seen that some of the young salmon, then two years and four months old, were either in the parr livery or had assumed the dress of silvery smolts, the latter in certain lights showing parr bands. On November 7, 1884, a smolt 1¼ lbs. weight jumped out of the pond, and from it about 100 eggs were expressed, and as they seemed to be ripe they were milted from a Lochleven trout.—On January 23, 1885, eighteen of these eggs hatched; the young were strong and healthy. November 11, 1884, about 12,000 Lochleven trout eggs were milted from one of the foregoing smolts, and they hatched January 28, 1885. December 1, 1884: 1500 eggs were taken from two of the foregoing smolts, and treated by the milt of one of the males. On the 9th, about 4000 eggs from these smolts were fertilised from one of the males, and on the 13th, 2500 smolt eggs were milted from a parr. Dr. Day further stated that pure salmon eggs in the Howietoun Fishery have been hatched, that the young have grown to parr, smolts, and grilse; that these latter have given eggs, and their eggs have been successfully hatched. Although time will yet be necessary before a definite reply can be given as to how these young salmon will thrive, how large they will eventually become in fresh water ponds, and whether from them a land-locked race may be expected—still the following points seem to be established. That male parrs or smolts may afford milt capable to fertilise ova; but, if taken from fish in their second season at thirty-two months of age, they are of insufficient power to produce vigorous fry. That female smolts, or grilse, may give eggs at thirty-two months of age, but those a season older are better adapted for the production of vigorous fry, where, to develope ova, a visit to the sea is not a physiological necessity. That young male salmon are more matured for breeding purposes than are young females of the same season's growth. That female salmonidæ under twenty-four months of age, although they may give ova most, are of little use for breeding purposes, the young, if produced, being generally weak or malformed. That at Howietoun, so far, hybrids between trout and salmon have proved to be sterile. Furthermore, it was stated that the size of eggs of salmonidæ vary with the age and condition of the parent, but as a rule older fish give larger ova than younger mothers. Even among the eggs of individual fish, variations occur in the size of the ova. From larger ova finer and rapidly growing fry are produced, consequently by a judicious selection of breeders, races may be improved, but it is only where segregation is efficiently carried out that such selection is possible.—A paper was afterwards read, Notes on some recently-discovered flowering plants from the interior of New Zealand, by the Rev. W. Colenso. In this the author describes and gives field notes on some eighteen supposed new species.

Institution of Civil Engineers, March 3.—Sir Frederick Bramwell, F.R.S., President, in the chair.—The paper read was on the construction of locomotive engines, and some results of their working on the London, Brighton, and South Coast Railway, by William Stroudley, M.Inst.C.E. The author, on his appointment to the London, Brighton, and South Coast Railway, in 1870, had to consider what kind of locomotive engine and rolling stock would best meet the requirements of the service; as, owing to the great increase and complication of the lines and traffic, the original primitive engines and rolling stock were not able to do so. He, therefore, in the same year designed a large goods engine, class "C.," arranging the detail so that they would enable him to construct the several classes illustrated, all the principal parts being interchangeable. Having had long experience with both outside- and inside-cylinder engines, he adopted inside cylinders, but placed the crankpins for the outside rods on the same side of the axle as the inside crank, the outside pin, however, having a shorter stroke; and he thus obtained the advantages of both systems. He adopted the method of putting the coupled wheels in front, instead of at the back as usual, which permitted the use of small trailing wheels, lightly weighted, and a short outside-coupling rod for the fast running engines, and also a much larger boiler than could be obtained when the coupled wheels were at the back. The author adopted a somewhat high centre of gravity, believing that it made the engine travel more easily upon the road, and more safely at high speeds; the slight rolling motion, caused by the irregularities of the road, having a much less disturbing influence than the violent lateral oscillation peculiar to engines with a low centre of gravity. The high centre of gravity also threw the greatest weight upon the outside or guiding wheel when passing around curves; and this relieved the inner wheels, and enabled them to slip readily. The author used six wheels in preference to a bogie for these engines, to avoid complication and unnecessary weight. The engines were very light for their power. Spiral springs were used for the middle axle, and these had a greater range than the end ones for the same weight. The two cylinders of the large engines were cast in one piece, with the valves placed below, giving lightness, closeness of centres, and easy exhaust and steam-passages. The crank-axle was the only disadvantage left in an inside cylinder, inside framed engine, and, when this was of good proportions, it offered but a small objection. Owing, however, to the narrow gauge of the rails in this country, the crank-axle could not be made so strong as it ought to be, or there would be no reason why a crank-axle should break. When the flanges of the driving-wheels were turned down thin, so as to avoid the side-shock given by crossings and check-rails, there only remained the strain of the steam upon the pistons to cause breakage; the action of this was precisely the same as the methods used by the late Sir William Fairbairn in testing to destruction the model tube for the Menai Bridge, by letting a heavy weight rest upon it suddenly at frequent intervals. The deflection, if sufficient, caused a crack at the weakest place, which gradually extended until fracture took place. This was precisely what occurred in the axle; the crack invariably commencing on the side of the axle opposite to that to which the steam was applied. The author, after thirty years' experience, believed that the separate parts of locomotives, including tires, axles, piston-rods, side-rods, bolts, cotters, and carriage and wagon axles, broke from the same cause; they did not break when carefully designed, and made with proper materials and workmanship. As the crank-axle could not be made of the proper strength, it was well to consider how to avoid, as far as possible, risk of accident by its failure. By making the axle-boxes and horn blocks deep and strong, giving large flat surfaces against the boss of the wheel and the outside of the crank arm, the driving-wheel was kept in position after the axle was broken, if the fracture occurred in the usual place, namely, through the inside web, near the crankpin, or through the centre part where it joined the inside web. An axle, broken in this manner, would run safely over any part of the road, except at a through-crossing, where the guiding-rail was lost, and the flange was liable to take the wrong side of the next point; this, however, had not happened in the author's experience. The author had always hooped the larger cranks, and had for some time hooped every new crank in the same proportion as adopted on the Great Northern Railway, thus reducing the risk to a minimum. The engines had been arranged that part of the exhaust steam might be turned into the tender or tanks, so that the feed-water might be heated. This was a special advantage in a tank engine, by increasing the total quantity of water; it also kept the water supply of greater purity, and it relieved the boiler of a certain amount of duty in heating the water from the ordinary temperature to that which feed-water required. The feed-pumps had been designed to meet the requirements of pumping hot feed-water. The proportions of the valve-gear gave an admission of 78 per cent. of steam in full gear, which could be reduced to 12 per cent. with excellent results; and as at high speeds the steam was never exhausted, the temperature of the cylinder was maintained, and as much steam was locked up in the cylinders as raised the pressure at the end of the stroke to near that in the steam chest. This made the engine run very smoothly at high speeds, and turned what would otherwise be an extravagant coal-burner into an economical machine. And for the same reason the compounding of fast-passenger or frequent-stopping locomotives was not likely to show much, if any, economy over a well-designed, simple engine. The case was different, however, in heavy goods engines, working with a late cut-off most of the time, and where the conditions approximated closely to those of a land or marine engine with a constant load. The back-pressure observed in the diagrams of high-speed locomotives was not therefore a defect, but an advantage, and the author accordingly used small steam-ports and short travel of slide-valve. These remarks as to back-pressure did not apply to the pressure in the exhaust pipes, where it should be as small as possible, but only to the back-pressure in the cylinder. The latter was greatest at high speeds, when a small volume of steam was passing through the cylinders, and small power was required, and least when

working full power with the smallest expansion. All the passenger engines and many of the goods engines were fitted with the Westinghouse automatic air-brake, as were also the whole of the carriages. This brake gave entire satisfaction and complete control of the trains. The author took considerable pains with the fittings and details when it was first introduced, and arranged the gear for the engines, so that the brake acted upon each wheel independently, allowing the springs freedom to act; or it acted upon the front of all the wheels, as in the tank engines, the brake of which was moved by hand as well as by the air-pressure. The Westinghouse air-pump had been fitted with a plunger at the bottom end of the rod, 1¼ inches in diameter, and this pumped water into the boilers of the goods engines when they were in sidings or were delayed by signals. For the express and large goods engines the greatest possible amount of heating-surface had been provided; the fire-box was capacious, with small tubes of considerable length in proportion to their diameter, little or no flame being generated with the coal used, and a very small amount of soot. The fuel which was found cheapest to consume in this locality was smokeless coal from South Wales, mixed with a small quantity of bituminous coal from Derbyshire. The boilers were made of the best Yorkshire iron, with plates having planed edges; holes were drilled after the plates had been bent; the joints were butt-joints, and they were hand riveted. The construction of the ash-pan and its dampers, perforated plates, water-supply, and the arrangement of fire-bars, brick arch, fire-door, and deflector, was shown. The indicator diagrams, taken by one of the Crosby Steam-Gauge and Valve Company's indicators, at various speeds, and under varying conditions of gradient, afforded a fair idea of the working capabilities of these engines, the economical value of which was best shown by quoting the consumption of fuel for the half-year ending June 30, 1884, when the average of the whole of the engines on this line was 29·74 lbs. per engine mile, including the coal used in raising steam. A great number of careful tests had been made of the amount of coal required to raise steam in the engines from cold-water, and also from the partially heated water when the boiler had not been emptied, and this amounted on an average to about 3 lbs. per mile run. Some doubts had been expressed as to the value of heating feed-water by the exhaust steam. The author, therefore, had a number of tests made with the ordinary heating-apparatus removed, and water led to the boilers by the feed-pumps, and in one series by a Borland's injector. The amount of power required to work the pumps was inappreciable; and the heated feed-water brought about reduction in the consumption of fuel to the extent of over 2½ lbs. per train-mile. It had also been found that heating the feed-water by direct contact of the steam did not, on this railway, injuriously affect the boiler-plates. With a view to ascertain what was the amount of power required to haul a train from Brighton to London, a complete set of 49 diagrams was taken from the engine "Gladstone," working an express train of twenty-three vehicles; the total weight of train and engine being 335 tons 14 cwt. A section of the line was given, and clearly illustrated the result, giving the H.P. at about every mile, the speed, and the gradient. The temperature of the gases in the smoke-box was taken at frequent intervals; also the degree of vacuum in the fire-box and in the smoke-box, and the quantity of water used out of the tender. To the latter had to be added the water condensed from the exhaust, which, from experiments, the author estimated at 20 per cent. This gave an evaporation of 12·95 lbs. of water per 1 lb. of coal, and 1 lb. of coal would convey 1 ton weight of the train 1·54 miles, at an average speed of 43·38 miles per hour, over the Brighton Railway, the rate of consumption being 2·03 lbs. of coal per H.P. per hour.

Chemical Society, March 5.—Dr. W. H. Perkin, F.R.S., President, in the chair.—The following papers were read:—On the conversion of Pelouze's nitrosulphates into hyponitrites and sulphites, by Prof. E. Divers, M.D., and Tamemasa Haga.—On the constitution of some non-saturated oxygenous salts and the reaction of phosphorous oxychloride with sulphites and nitrites, by Prof. E. Divers, M.D.—The illuminating power of hydrocarbons. I. Ethane and propane, by Percy F. Frankland, Ph.D., B.Sc.—On benzylacetic acid and some of its derivatives, Part III., by Dr. W. H. Perkin, jun.

Anthropological Institute, March 24.—Francis Galton, F.R.S., President, in the chair.—The election of the following gentlemen was announced:—F. D. Mocatta, the Hon. Cecil Duncombe, J. G. Fraser, M.A.—A paper was read by A. J. Duffield on the inhabitants of New Ireland and the archipelago. The author first deals with the assumption that the superior races, that they retain inherited powers which have become weak by lack of use, and that those wards can be intellectual powers can be easily restored. The food of the natives is chiefly vegetable, but they now and then kill the bush-pig, small native swine—the opossum—and poultry, which is a delicacy. The climate is humid and unhealthy; the people are small in size, and light in weight. Their usual color is a dark brown, but they are a mixed race; the hair is curly and glossy. The tattooing and cuttings on the flesh are confined to the women and the headmen. The men go naked, but the women wear "aprons" of grass tufts hanging behind, suspended from cincturcs made of banana strings or cane-made thread; they bleach their hair and paint their teeth with coloured earths. They speak a language which is very musical and familiar, in which is found a few words of Arabic and Spanish words.—Mr. R. Bradenell Carter read a paper on vision-testing; and Mr. C. Roberts read a paper on the same subject.

Dublin

Royal Society, January 19.—Section of Physical and Experimental Science.—Prof. C. A. Cameron, M.D., in the chair.—Prof. Emerson Reynolds, M.D., F.R.S., gave an account of the selenium analogue of the sulphur urea—thiocarbamide—he discovered some years ago. The author, having recently prepared a considerable quantity of cyanamide, and being aware that other chemists had failed to produce thiocarbamide by the molecular change of ammonium selenocyanate, decided to examine the action of hydrogen selenide on cyanamide, as it is well known that thiocarbamide can be easily built according to the equation $H_2S + \begin{matrix} CN \\ H \end{matrix} \Big\} N = CS \Big\langle \begin{matrix} NH_2 \\ NH_2 \end{matrix}$. Ten grams of cyanamide were dissolved in 50 cc. of absolute ether and a slow current of hydrogen selenide was passed through the solution under a pressure of about 60 mm. of mercury. The gas was slowly absorbed, and at first some selenium separated from the liquid, but on continuing the treatment beautiful colourless crystals separated on the sides of the vessel. These were drained from the ethereal liquid, and when exposed to air were found to be easily reddened by the action of light. They were dissolved in a small quantity of hot water, the solution filtered, and then cooled, when beautiful silky crystals separated which very closely resembled thiocarbamide in appearance and mode of crystallisation. The purified compound proved to be $CSe(NH_2)_2$. The author learned, however, from the January number of the *Journal* of the Chemical Society of London that M. A. Verneuil had just published an account of the same body in the *Bulletin* of the Paris Society. Dr. Emerson Reynolds, therefore, did not continue his investigation, as he believed M. Verneuil to be fully entitled to priority, but contented himself with the exhibition to the society of the specimens of selenocarbamide produced in the Dublin University Laboratory.—Also a model illustrating some properties of the ether, by Prof. G. F. FitzGerald, M.A., F.R.S. The model consisted of 3 series of wheels arranged at equal distances along parallel rods, and affixed perpendicularly into a board. The wheels were connected together by indiarubber bands, each wheel being so connected with its four neighbours. Under these circumstances it was shown that if any wheel were turned all the wheels would move simultaneously, and that, except for friction on the rods, they would all turn equally. It was explained that the model also exhibited properties of the ether itself and did not exhibit the connections of matter with ether. A region within which the bands did not slip represented a non-conducting region; the differences of elasticity of the bands represented differences of specific inductive capacity, slipping of the bands represented a conducting region, and complete absence of bands represented a perfectly conducting region. When bands were removed from a certain region and left around it a line of bands left, and all around outside this again a condensing region. If a conducting line connected these regions the wheels on this line might be turned in opposite directions, and when this is done all the non-conducting region is thrown into a state of stress by all the wheels not rotating equal amounts, so that the bands are tight on one side of a pair of wheels and loose on the opposite side. It was explained that this exhibited

ination of the medium between two oppositely charged
actors, the direction of polarisation being at right angles
ese bands—*i.e.*, in the line joining the conductors—the
am in this state representing a charged Leyden jar, the two
site electrifications being represented by the tight and loose
s, one conductor being bounded entirely by tight bands and
he other by loose ones, and the electric displacement of
rell being represented by the difference between the two
of a band. If the bands along any line between the
onductors slipped, all the energy of the medium was spent
this line in friction, and this represented a discharge along
ne. This energy was conveyed into the line of discharge by
le and not along its length in accordance with what Prof.
lling has recently shown to be the case in all electric currents.
resistance along the line of discharge were sufficiently small
omentum of the wheels would carry them beyond their
on of equilibrium and the well-known phenomenon of an
uating discharge would be represented. This led to the
vation that the magnetic displacement was represented by
ngular velocity of rotation of the wheels and the self-
tion by their momentum. It was remarked that the
anical attraction between the two conductors was not
ented, but it was explained that as this depends on the
ction of matter with ether it would require more compli-
mechanism. It was, however, pointed out that by
sing the wheels slightly distorted by the stress, and by
sing a thread wound round them and each end connected
the material of a conductor, a force would be produced
ng the conductors together owing to the circumfer-
of a distorted wheel being longer than of an un-
ted one. This force would be proportional to the
e of the distortion, a necessary condition not satisfied by
ary stresses, and would be, if exerted between two infinite
s, independent of their distance apart, and as must represent
e varying inversely as the square of the distance. Return-
the electric currents, it was shown that by turning the
e at any point of a conducting circuit the whole region was
with turning wheels—*i.e.*, with magnetic displacement—and
if a resistance were introduced at any point of the circuit,
ergy would be transferred to that point through the medium
mer by the aide of the conductor. If two independent
cting circuits existed near one another it was shown that
ementum of induced currents were represented. It was
ted that the mechanical force was not represented, as it
ded upon the connection between matter and ether,
ut it might be looked for as in some way depend-
n the centrifugal force arising from the rotations.
equations representing the energy of the model are
same form as those of Maxwell representing the
of the ether when limited by the consideration that the
was only in one plane. It was explained that a frictionless
model whose energy could be represented by the same
ons as Maxwell's could not be constructed with indiarubber
but might be constructed by means of wheels pumping
through pipes. This led to the observation that the
gation of waves by transverse vibrations could be illustrated
model, and it was explained how a sudden turning of any
wheels would start a wave-propagation whose direction
pagation was at right angles to the directions of magnetic
sement and of electric displacement, the former repre-
by the axes of rotation and the latter by the line joining
entres of a tight and loose band. It would be pos-
heoretically to construct a model illustrating the laws
ection and refraction of light even at the surfaces of
line media, and to reproduce conical refraction. It was
ted that by twisting the medium the rotatory polarisation
ctz might be represented, and that probably a mechanism
be introduced by which the rotation of other wheels or of
ring besides the wheels being altered by the rotation of
cels, a reaction of the former on the latter would repro-
magnetic rotatory polarisation. It was pointed out that
magnetic rotatory polarisation and dispersion were due to a
n of the medium during the wave-propagation and not to
ge of the medium independent of the wave-propagation.
explained that it was not to be supposed that the ether
nstructed of wheels and indiarubber bands, nor even of
pumping fluid in pipes, but it was pointed out that some
ties of the ether might be gathered from the model if it be
d that the qualities of the ether represented by symbols
g the laws of rotation for instance are really of the nature
tion. If this be so the ether must be such that any part
of it can rotate as often as it likes provided all the neighbouring parts rotate equally and the electrostatic stresses in the ether must be due to the difference of rotation of its parts. If the ether be a perfect liquid it can only have such properties as represent rigidity by being in motion, and it was explained that many electrical phenomena might be illustrated by the polarisation of the vortical motions in a vortex-sponge. Sir Wm. Thomson has pointed out that such a state of polarisation as a single vortex region in the centre of a cylindrical box will not of itself change unless it can spread its energy on the box, which is quite analogous to the fact that the energy of the polarisation of the ether does not disappear unless it can produce heat or mechanical or other forms of energy. It was also pointed out that forces depending on small vortices vanished at small distances from them and that hence the forces depending on their polarisation between two infinite planes would depend on the polarisation and not on the distance between the planes, and so must be of the nature of forces varying inversely as the square of the distance. It was explained that the modes of polarisation of vortices were sufficient to explain both electrical, magnetic, cohesional and chemical forces. It was finally reiterated that the only possible way of giving anything of the nature of rigidity to a perfect liquid was by conferring motion on it and that it seemed likely that any mechanical properties could be conveyed by suitably chosen motions. This was quite in accordance with Sir Wm. Thomson's suggestive address to Section A at Montreal.

Natural Science Section.—V. Ball, M.A., F.R.S., in the chair.—On the physical characters of calcareous and siliceous sponge spicules and other structures, by Prof. W. J. Sollas, M.A., D.Sc., F.R.S.E., F.G.S.—The refractive index of a siliceous sponge spicule, diatom, or other siliceous organic body is determined by immersing it in liquids of different refractive indexes until one is found in which it ceases to be visible under the microscope. The refractive index of this liquid gives that sought for. The siliceous matter of organisms has a refractive index of 1·449, which is that of some kinds of opal or cylindrical silica. The refractive indexes of calcareous sponge spicules are found in a similar manner, but as these are biaxial it is necessary to examine them between crossed Nicols; $r_1 = 1·485$, $r_2 = 1·656$. These indexes agree with those of calcite. This method of obtaining refractive indexes is applicable to mineral bodies; the glass of the Krakatoa explosion is thus found to have a refractive index of 1·51. Leucite can be thus readily distinguished from analcime and calcite from aragonite. The specific gravity of calcareous spicules (1·62) and that of foraminifers were found by an adaption of the Sonstedt solution method to use with the microscope. The perforate foraminifera have a sp. gr. of 2·65 to 2·67, the imperforate of 2·7 to 2·72, calcite being taken as 2·7. The structure of calcareous spicules was shown by a study of the extinction angles between crossed Nicols, by the development of cleavage planes, and each figures to be purely crystalline. Each spicule is a single calcite individual with its optic axis definitely related to its form. The acerate spicules of calci-sponges are distinguished from those of the siliceous sponges by their form, the former often presenting an oval or rhombidial transverse section. The large spicules of the Pharetrones agree with those of the Calcisponges, with which, therefore, this fossil group must be associated.—On some Trilobites from the Cambro-Silurian rocks of the County Clare by W. H. Baily, F.C.S.—Notes on the coalfields of Leinster and Tipperary by G. H. Kinahan, M.R.I.A.

CAMBRIDGE

Philosophical Society, March 2.—Prof. Foster, President, in the chair.—The following communications were made:—On some theorems in tides and long-waves, by the Rev. E. Hill. Elementary considerations were given from which it might be inferred that when a disturbing body produces a semi-diurnal tide in an equatorial canal, the point nearest to the disturbing body will be a point of low tide or high tide according to the depth of the canal. A general explanation was given of the inference of the depth of a canal on the speed of a long wave traversing it. It was shown that the ordinary formula for this speed might be deduced from the ordinary differential equation of motion without integration.—On the electrical resistance of platinum at high temperatures, by Mr. W. N. Shaw.—On an automatic mechanical arrangement for maintaining a constant high potential, by Mr. Threlfall. A water-motor of the Thirlmere type is allowed to settle down to a constant velocity by means of the resistance of a fan which is worked by the motor.

The motor thus governed rotates a shaft on which is a copper disc and two pulleys. The copper disk is placed between the poles of a large electro-magnet; and the second pulley serves to give motion by means of an india-rubber band to a replenisher whose dimensions are determined by the special conditions of the experiment for which the apparatus is to be employed. The regulator, mounted on a box in which is a condenser, consists of a fixed and movable disk, the latter suspended from a spiral spring and carrying a wire across its back turned down at its two ends. The disks are connected with the poles of the condenser, the movable one being put to earth. By means of a Weber suspension arrangement mounted on the top of a guard-hole which protects the spiral spring from currents of air, the attracted disk can be adjusted so that when the difference of potentials arrives at the required value, the wire dips into two mercury cups and so short-circuits a high resistance. By this means a strong current is allowed to flow through the electro-magnet and act as a brake on the copper disk; this causes the velocity of the engine to change and a replenisher to revolve more slowly. When the potentials have fallen sufficiently by leakage or otherwise, the contact at the mercury cups is broken and the motor is enabled to rotate at a higher rate of speed. By this means the potential difference is kept between certain limits depending on the sensibility of the arrangement, and this is increased by having the disks close together and the contact points made of aluminium instead of platinum. Such an apparatus is of use in maintaining condensers, &c., subject to leakage at a constant high potential.

PARIS

Academy of Sciences, March 16.—M. Bouley, President, in the chair.—Reaction of bromine on the chlorides and on hydrochloric acid. A new class of perbromides by M. Berthelot. Fresh experiments made by the author show that the reaction of bromine on the chlorides always liberates heat in the same way as the inverse reaction. In both cases the transformation of the system is always exothermic. Hydrochloric acid and highly concentrated chlorides dissolve bromine in large quantities with liberation of heat, attesting the existence of combinations formed by addition (perbromides of chlorides).—A morphological comparison of Limax (*L. Agrestis, Cinereus* and *Gagates*) with Testacella (*T. haliotidea* and *Maugei*), by M. H. de Lacaze-Duthiers.—On the solubility of the sulphurets of carbon and of chloroform, by MM. G. Chancel and F. Parmentier. The solubility of the sulphuret of carbon in water is shown to diminish according as the temperature is raised. But that of chloroform presents a decreasing solubility from 0° to about 30° C., thenceforth increasing towards its boiling-point.—On the influence of the perturbations in determining the orbits of celestial bodies, by M. E. Vicaire.—A reply to M. Boiteau on the treatment of phylloxera and its winter eggs by washings and sulphur, by M. P. de Lafitte.—Records of the Scientific Mission to Cape Horn (1882-83); Vol. B, Meteorology, by M. J. Lephay.—Note on the Abelian functions, by M. H. Poincaré.—On the theory of matrices, by M. Ed. Weyr.—On the canonical types of the ternary quadratic forms of differentials whose discriminant is null, by M. G. Königs.—On the electric differences between fluids, and on the part played by the atmosphere in the electrometric measurement of these differences, by MM. E. Bichat and R. Blondlot.—A thermo-chemical study of the fluosilicate of ammoniac; action of the fluoride of silicium on the fluoride of ammonium, and on ammoniac, by M. Ch. Trechot.—Description of a new process for hardening plaster of Paris, by M. Julhe. By the process here described a plaster is produced which may be substituted for wood in floorings, being equally durable and four times cheaper than oak.—Bromuretted substitution of phenolic hydrogen: bromuretted tribromophenol, by M. E. Werner.—On Fromherz's fluid, by M. E. J. Maumené.—On the chemical composition and therapeutic properties of *Artemisia gallica*, Willdenow, by MM. Ed. Heckel and Fr. Schlagdenhauffen.—Physiological action of the hexahydride of β-collidine or isocicutine, by MM. Rochefontaine and Reichsner de Coninck. From experiments made on the frog and guinea-pig the authors find that this substance possesses a physiological action analogous to that of the alkaloid of hemlock (Cicuta). Hence they propose the alternative name of "isocicutine," recalling at once its chief chemical and physiological properties.—Definition, classification, and notation of colours, by M. J. Charpentier. A system of notation and classification is suggested, by means of which a thousand colours may be formulated by the series of natural numbers from 0 to 999, where each cipher takes a precise meaning in virtue of its position. The name of the colour would simply be that of the number symbolising it, and the cube might be called the "cubic classification," from the geometrical representation by which it may be best figured.—On the glands and lymphatic vessels entering into the composition of the organ in birds known as the purse of Fabricius, by E. Retterer.—On the physiological effect produced by the action of turning eggs during incubation, by M. Dareste. From experiments made with artificial incubators, the author finds that eggs not turned two or three times a day all perish invariably. The effect of this act on the embryo is explained, and the reason why the bird accounted for on strictly physiological grounds.—On the formation of the carbonate of zinc: their normal association with the calamitic formations explained, by M. Dieulafait.—On the Miliolidæ of the Chalk formations, by MM. Munier Chalmas and Schlumberger. Idalina, Periloculina, and Lacazina, three new genera from the Upper Chalk of Provence, are described and referred to the family of the Miliolidæ.—The channels and lagoons on the east coast of Madagascar, by M. A. Grandidier. The inlets and lacustrine formations are explained by the position of the main water parting, which is usually placed about the centre of Madagascar, but which the author shows is situated much nearer to the east than to the west coast.

VIENNA

Imperial Academy of Sciences, January 22.—An analysis of andesin of Frifail (Carinthia), by K. Maly.—On the self-purification of natural waters, by F. Emich.—On the action of bile acids on glutin and glutin "peptones," by the same.—On the products obtained by reduction of nitrocoumic bodies, and on azoamidnitric acids, by J. V. Janovsky.—On the astronomical knowledge of the South Arabian Cahyles, by E. Glaser.—On oxydracetic acid, by L. Haitinger.—Geological researches on the grauwacke formations of the North-East Alps, especially regarding the Semering region, by F. Toula.—On the meteorological observations made at the Austrian arctic station at Jan Mayen during 1882 and 1883, by A. Sobiezky.—On tide observations made in 1882-83 at Jan Mayen, by A. Bobrik.—On the results of Jan Mayen carried out by the Austrian Arctic Expedition in the same.

In Casks, 12/6 per 9 gals. In Bottle, 3/3 per doz. Impl. Pts.*
* Bottles charged 2/- per doz., and allowed at the same rate if returned; but they must be paid for with the Beer.
Neither sugar, saccharum, nor any of the many new Brewing Materials are used in the manufacture of the "S. N." Stout; it is Brewed entirely from the finest Malt and Hops; it is, too, more hopped than Stout is generally; therefore, besides being very nutritious, it is an excellent Tonic and particularly suited for invalids, ladies nursing, or anyone requiring a good strengthening beverage. It is a "Sound Nutritious" Tonic, and very much recommended by Medical men.

SPECIALITIES for the MICROSCOPE

	s.	d.
Five typical examples of blood on one slide	5	0
Mature Eggs of Flounder, showing young fish	1	6
Brilliant Eyes of Spiders mounted without pressure	1	6
Section through Jaw of Cat, all the teeth *in situ*	6	0
Involuntary Muscle, Arteries injected	1	9
Foraminifera, 5 different species in separate groups, named on one slide	1	0

40,000 Specimens illustrative of Anatomy, Physiology, Botany, Entomology, Geology, and Mineralogy. 32, 34, 36, 38, 40, 42, and 44 pp. 8vo, and 48 pp. 4to, gratis and post free.

	s.	d.
The Lord's Prayer, engraved on glass, with 1 thousand on the side of one Bible to the square inch	1	0
Dr. Koch's Comma Bacillus in Asiatic Cholera	1	0
Variety of groups of Foraminifera, all named	1	0
Groups of Polycistina from Barbadoes	1	0
Type Slide of Diatomaceæ, 100 species, with list of names	2	0

SPECIALLY BEAUTIFUL SLIDES FOR *MOUNTERS, &c.*

Artistically-arranged groups, composed of Diatoms, Wheels of Chirodota, Anchors and Plates of Synapta, Scales of Butterflies, &c. W. WATSON & SONS call special attention to these Slides, their beauty being unsurpassed, and most suitable as Exhibition Slides. Prices in Case, 10s. 6d., 15s. 0d., 21s. 0d., 31s. 6d., and 42s. 0d. each.

Scales and Hairs of Insects arranged as a Sprig of Flowers ... ... 5s. 0d. each, or 50s. 0d. per doz.

Do. Do. Bouquets or Vases of Flowers ... ... 10s. 6d. each, or 105s. 0d. per doz.

Cut Sections ready for Mounting. The following now ready:—Human Spleen, Malpighian bodies Injected; Human Medulla Oblongata, stained; Petiole of Cinnamon. Price, 6 Sections in tube, 1s., postage 1d. extra.

NEW CLASSIFIED LIST of OBJECTS for the MICROSCOPE (including the recently acquired Stock of Mr. E. Wilson late of Tollington Road, Holloway) sent post free to any part of the world, on application to

W. WATSON & SONS, 313, HIGH HOLBORN, LONDON.

TWO DOORS FROM CHANCERY LANE. ESTABLISHED 1837.

THE "EXCELSIOR"

PATENT SPRING MATTRESS.

AWARDS: TEN PRIZE MEDALS, FOURTEEN CERTIFICATES OF MERIT

The principle of arrangement permits the free movement of one sleeper without inconvenience to the other, admits of complete isolation of each, and *effectually prevents depression in the centre.*

THE "EXCELSIOR" AND "MATLOCK" BED-RESTS

THE "EXCELSIOR" & "MATLOCK" COUCHES.

Retail from Cabinet Makers, Upholsterers, &c.

THE NEW PATENT

WOVEN WIRE MATTRESS.

The leading peculiarity of this Mattress is the combination of a woven wire central portion with ... springs of great strength and reliable temper, ... advantages possessed by no other make. The ... springs obviate the tendency in all woven wire ... to become hollow and so cause sleepers to roll ... middle of the bed.

Illustrated Descriptive Circulars and Price Lists

CHORLTON & DUGDALE, MANCHESTER.

Collection of Six Fasciated Stems:—Strawberry, Sweet Pea, Tropæolum, Thistle, Stonecrop, and Celosia, 1s.

Vertical Section of the Male Perichætum and Antheridia of Atrichum undulatum, 1s.

Vertical Sections of the Apothecia of Usnea barbata and Lecanora tartarea, showing Asci, 1s. each.

Trans. sect. of Esparto Grass (remarkable arrangement of Fibre), 1s.

Pezizula tripa, portion of Thallus, beautiful arrangement of Chlorophyl granules, 1s.

Teleutospores of Puccinia graminis, 1s.

Spores and Elaters of Anoura plagiis (Jungermanneæ), 1s.

Stained and Isolated Conidia-bearing Hyphæ of a Micro-fungus, probably Polyactis cana, 1s.

When ordered off the Catalogue (except where special series are affixed) the prices are as follows:—1s. each, 6s. a dozen, 25s. per 50, £2 per 100.

MICRO-SLIDES FOR SCIENCE CLASSES.

Section of stem of the Lily (Nymphæa alba), showing Diatoms highly Polar, 1s.

MR. PIFFARD'S PATENT COUNTER-SUNK SLIPS now on Sale. Two sizes, 3s. and 2s. 6d. per dozen. They are described in the *Journal of the Royal Microscopical Society*, August 1884:—

PIFFARD'S SLIDES.—Mr. B. Filled the ... slide, which is made by forming with a diamond ... in an ordinary slide. In this the object is placed and ... this glass. The upper surface of the slide is then ... the cover-glass being even with the slide. There is ... cover-glass and object being knocked off; and the ... tiful diffusion of light.

REMITTANCE WITH ORDER. ENLARGED CATALOGUE READY, POST FREE.

LECTURE ARRANGEMENTS AFTER EASTER, 1885.

Lecture Hour, 3 o'clock p.m.

Prof. ARTHUR GAMGEE, M.D., F.R.S., Fullerian Professor of Physiology, R.I.—Eight Lectures on Digestion and Nutrition; on Tuesdays, April 14 to June 2. One Guinea the Course.

Prof. TYNDALL, D.C.L., LL.D., F.R.S., M.R.I.—Five Lectures on Natural Forces and Energies; on Thursdays, April 16, to May 14. One Guinea.

Prof. C. MEYMOTT TIDY, M.B., F.C.S., M.R.I.—Three Lectures on Poisons in Relation to their Chemical Constitution and to Vital Functions; on Thursdays, May 21, 28, June 4. Half-a-Guinea.

WILLIAM LASSELL, Esq., F.R.S.—Four Lectures on Fly-traps and their Allies, in the Present and in the Past; on Saturdays, April 25, 29, May 2, 9. Half-a-Guinea.

Prof. WILLIAM ODLING, M.A., F.R.S., M.R.I.—Two Lectures on Organic Septics and Antiseptics; on Saturdays, May 16, 23. Half-a-Guinea.

Rev. C. TAYLOR, D.D., Master of St. John's College, Cambridge—Two Lectures on a Lately Discovered Document, possibly of the First Century, entitled "The Teaching of the Twelve Apostles," with Illustrations from the Talmud; on Saturdays, May 30, June 6. Half-a-Guinea.

Subscription (to non-Members) to all the Courses during the Season, Two Guineas. Tickets issued daily.

Members may purchase not less than Three Single Lecture Tickets, available for any Lecture, for Half-a-Guinea.

The FRIDAY EVENING MEETINGS will be resumed on April 17, at 9 p.m., when Prof. S. P. LANGLEY will give a Discourse on Sunlight and the Earth's Atmosphere, at 9 p.m.

ST. THOMAS'S HOSPITAL MEDICAL COLLEGE,

ALBERT EMBANKMENT, S.E.

The Summer Session will commence on May 2. Students who have passed a Preliminary Examination are informed that, under the Regulations of the Examining Board in England, it is an advantage to begin in the Summer Session; those entering in summer are also eligible to compete for the Science Scholarships of £100 and £60, awarded in October.

There are numerous Prizes and Scholarships, and all Appointments are open to Students without extra charge.

Special Classes for the Examinations of the University of London are held throughout the year. A Register of Approved Lodgings and of Private Families receiving Students to reside is kept in the Secretary's office.

Prospectus and all particulars can be obtained from the Medical Secretary, Mr. G. RENDLE.

W. M. ORD, Dean

THE MIDDLESEX HOSPITAL MEDICAL SCHOOL.

SUMMER SESSION, 1885.

Lectures and Clinical Instruction in the Wards will commence on May 1. A Scholarship, value £25, will be offered for Competition to Students commencing their Medical Education in May. The Examination will be in Classics, Mathematics, or Natural Science, and will commence on April 29. Two Entrance Scholarships of the Annual Value of £25 and £20 respectively, tenable for two years, and a Science Scholarship value £30, will be offered for competition at the beginning of the Winter Session.

For Prospectus containing Particulars as to other Scholarships, Resident Appointments, Fees, &c., apply to the DEAN, or the Resident Medical Officer at the Hospital

ANDREW CLARK, Dean.

ST. GEORGE'S HOSPITAL MEDICAL SCHOOL.

HYDE PARK CORNER, S.W.

The Summer Session will commence on FRIDAY, May 1.

Five Entrance Scholarships—

The William Brown £100 Exhibition;
The William Brown £40 Exhibition;
Two Brackenbury Prizes, £50 each;

And various other Prizes, are open to Competition.

Full Particulars, with the Subjects of Examination, may be obtained on application to

WILLIAM WADHAM, M.D., Dean of the School.

C. D. AHRENS,

PRISM WORKER AND PRACTICAL OPTICIAN,

In the list are set to Jacuritis, Spongilla flavicilla, Stephanoceros, Euchlanis, Conochilus, Volvox globator, Diatoms and Desmids; also Hydra, Asellus, Fresh-water Crayfish, and other Specimens for (Huxley and Martin's) Botany week.

Weekly Announcements will be made in this place of Contents for supplying.

Specimen Tube, One Shilling, post free.

Twenty-six Tubes in course of Six Months for Subscription £1 10s. or Twelve Tubes for 10s. 6d.

Portfolio of Drawings, Ten Parts, 2s. each.

LONDON HOSPITAL AND MEDICAL COLLEGE,

MILE END, E.

The SUMMER SESSION will commence on Friday, May 1. New Students are advised that under the new regulations of the Royal College of Physicians and the Royal College of Surgeons, it is compulsory for Students who agree to enter for the Summer Session. Students are hereby notified that they are eligible for the Entrance Scholarships in September.

The Hospital contains nearly 800 beds, and is the largest provincial Hospital in Great Britain.

General Fee for Lectures and Hospital Practice, 50 guineas in one payment, or 100 guineas in three instalments. The Resident and other Hospital appointments are free to full Students.

Special entries may be made for Medical and Surgical Practice, and for a course of Practical Surgery.

The London Hospital is now in direct communication by rail with all parts of the Metropolis, and the Metropolitan, Metropolitan District, South Eastern, and East London Railways have stations within a few minutes' walk of the Hospital and College.

For Prospectus and particulars apply to

MUNRO SCOTT, Secretary.

PRIZE OF ONE HUNDRED POUNDS.

THE JOURNAL OF
ANATOMY AND PHYSIOLOGY.

POLARISATION OF LIGHT By W.

MUTUAL LIFE ASSURANCE.

SCOTTISH PROVIDENT INSTITUTION.

EDINBURGH—6, ST. ANDREW SQUARE. LONDON OFFICE—17, KING WILLIAM STREET, E.C.

The ATTENTION of ASSURERS is directed to the SPECIAL ADVANTAGES obtainable in this Society, in respect of
ECONOMY—EQUITY—SAFETY.

ECONOMY.—The Premiums are, in many cases, 20 to 25 per cent. under the usual rates, so that a Policy for £1250 may generally be had for the yearly payment which would elsewhere assure £1000 only.

EQUITY.—The whole Surplus is divisible among the Policy-holders themselves, on an equitable principle—no shareholder given to those by whose early death there is a loss to the other Members. From this source large additions have been made and may be expected in the future.

SAFETY.—The Business (which for ten years has exceeded a Million yearly) is of the most select character, and is conducted at the smallest cost.

The expenses, which are less than in any Office transacting so large a business, were last year under 9 per cent. of the Premiums, and little over 6 per cent. of the year's Income.

THE FUNDS accumulated from Premiums exceed £5,000,000, the increase last year being £333,383.

Only two Offices in the Kingdom (both older) have as large a Fund.

Claims under Policies now payable a Month after Proof.

Reports, with Tables of Premiums, &c., on Application.

J. MUIR LEITCH, London Secretary.

JAMES WATSON, Manager.

WESLEY COLLEGE, SHEFFIELD.

great value as a practical guide. As such, it takes what it, in some respects, a new departure: it rejects the familiar notion that as storms are mere derangements of the system of winds, they deserve, in a systematic study, nothing more than an incidental notice; and it puts prominently forward the idea that, on the contrary, they ought to be studied in very full detail; because, as it argues, the derangements are rather exaggerations than alterations of the system, and are thus capable of serving as a microscope for the student's clearer instruction. It is an idea which has been well and fully worked out; and with a care and industry which supply the reader with an exhaustless mine of illustration and example.

J. K. L.

MUIR'S "PRINCIPLES OF CHEMISTRY"

Principles of Chemistry. By M. M. Pattison Muir, (Cambridge University Press, 1884.)

DURING the last two decades chemistry has made, possibly, its greatest strides, and has unquestionably drawn to itself a greater following of students in this country than in any previous period. One result of that has been a multiplication of text-books such as perhaps no other science can show. This is only as it should be in the case of a living and progressing science like chemistry. But if one masters the style of text-book produced during this period it becomes painfully doubtful whether they as a whole have kept abreast of the mental capacity which should have been, and undoubtedly has, developed during this period.

Chemistry is certainly a practical science, and that in a very full acceptation of the term; but at the same time it has a history as a practical and especially as a theoretical or mental study second to none, and the unsatisfactory part of the majority of the text-books of modern date is that this growth and development, and the invaluable effect of this as a mental training, have been almost completely ignored.

As mathematical men have been heard to say when going through a course of chemical drudgery, "there seems to be nothing but a lot of isolated facts to learn up." And one cannot be surprised at the remark. The text-books may be roughly divided into two sorts—those of a dictionary character and those intended as an introductory or elementary teacher; the former fulfil their intention, which can scarcely be said of the latter, in which the points of principal theoretical interest are "atomicity" and "atomic and molecular combination," and various ways of writing "formulæ."

It is much to be feared that the teaching of the past few years in this country in chemistry has assumed such an intensely "practical" form that philosophical chemistry has been left very much out in the cold. The numerous examinations in which practical work is required has raised up, unfortunately, an army of "test tubers" and crammers whose theoretical knowledge is of the slenderest. Without in the least wishing to underrate the value of practical work, it does certainly appear, looking only at the chemical literature of the past few years, that theoretical chemistry has to a great extent receded from view in favour of practical, and that of a not very thorough

In the present book Mr. Muir has made up for the lacking in our text-books, and has certainly rendered a real service to the English student who aspires to be something more than a mere test-tuber and writer of graphic formulæ.

As the author informs us, the book is intended for students who already have some elementary acquaintance with the science, and is meant to give "a fairly complete account of the present state of knowledge regarding the principles and general laws of chemistry." And in this the author has certainly succeeded; for it may with certainty be said that we have not a more comprehensive work of the kind in the language. For although it does not pretend to the rank of a Kopp, still it quite fills the place in English chemical literature that Lothar Meyer's "Modernen Chemie" does in the German, which latter work, the author tells us, he has made "free use of."

The subject-matter of the book is necessarily extensive, and has been divided into two main parts—Chemical Statics and Chemical Kinetics. The historical method of treatment adopted cannot fail to be appreciated by the real student who aspires to be something more than a mere recipient of dry facts.

The chapter on Atomic and Molecular Systems and on the Application of Physical Methods to Questions of Chemical Statics, as well as that on Affinity, are condensations from all the most recent works on the subject, and are, as a rule, clear and concise. The references to originals, &c., &c., are numerous, and the mechanical errors throughout the work are surprisingly few.

The book should be very useful to students training for teachers, and who may not have the advantage of reference to original literature on the numerous subjects treated of.

OUR BOOK SHELF

Eine Weltreise. Plaudereien aus fünf Zwölfjähriger Erdumsegelung von Dr. Hans Meyer. (Leipzig: Verlag des Bibliographischen Instituts, 1885.)

THIS handsome volume is something more than the work of a "globe-trotter," even of a very amusing "globe-trotter." Dr. Meyer sailed down the Danube to Constantinople, thence to Athens, Syria (where he visited Smyrna, Beyrout, Damascus, and Jerusalem), Egypt, and by the Red Sea to Bombay. He then travelled through Southern India to Calcutta, and from Madras through Southern India to Ceylon. The journey in the Far East included Singapore, a considerable portion of Java, the Philippines, Hong Kong, Shanghai, and Japan. Thence he reached the United States, through a large part of which he travelled, Mexico, Cuba, and so back to Europe. The journey was more extensive than the usual modern journey around the globe; Java appears to have been thoroughly visited, but the only place in which the work displays any mark of originality is in the Philippines. The scenes and experiences by the way are described with much liveliness, but soon after his arrival in Manilla he made a journey into the northern mountainous region of Luzon, for the purpose of studying the Igorrotes and other tribes having their habitat there. The story of the journey, which occupied about three months, is full of interest, and the ethnology of these tribes is discussed in a special appendix. Prof. Blumentritt, the Austrian scholar, who has devoted many years to the study of the archipelago, especially to the vast Spanish literature of the seventeenth and eighteenth centuries relating to it, comes to the following conclusion as to

nography. The authoctonous population of the Phil-
ines, the Negritos, were driven back by two Malay
asions, and are now to be found only in isolated
nnants scattered throughout the islands of the archi-
ago. By the first invasion the Negritos were forced
m the coast into the interior, where they remained
disturbed until the second Malay irruption. This
ve the first Malay invaders in their turn from the
st, and the descendants of the new comers still occupy
ports and harbours to this day. The Negritos were
er destroyed by wars with the first Malays, or com-
ely absorbed by marriage with them, that now no
es of them are to be found. The Malays of the first
asion came from Borneo, and are found to-day in the
ntain districts of Luzon, under various tribal names,
h as the Tingianes, Igorrotos, Guinanes, Apayos,
ncas, Calingas, Gaddanes, &c.; while the second
aders, now known as Tagals, Pampangos, Visayas,
anes, Cagayanes, &c., inhabit the coast regions, where
were found by the Spaniards in the third quarter of
sixteenth century. Naturally the various tribes were
ble to prevent being influenced by each other, as well
rom without, and to this we must attribute similarities
nany respects, and especially in religion, which mark
Malays of the whole archipelago. Allowance too
to be made for the influence of the Chinese, perhaps
of the Japanese, on the tribes living on the coast long
r to the Spanish invasion. The inhabitants of the
r, the Malays of the second invasion, for the most
profess Christianity now, and are well known, but the
ns of the interior, the Borneo Malays, who, accord-
to Prof. Blumentritt's theory, formed the first invasion,
e never been thoroughly investigated, and this circum-
ce led Dr. Meyer to spend three months among the
rotos. The appendix in which he records his obser-
ons is very full. It discusses the name and extent of
Igorrotos, their territory, and its climate, their build,
e of dressing the hair, and tattooing (which is far more
ariate than that of even the Japanese grooms, and is
ably the most complicated in the world), their dress,
ments, weapons, villages, huts, agriculture, and
e-breeding, food, and drink, domestic utensils, art,
; customs at birth, and marriage, and death; their
is and religion; head-hunting; war customs, festivals,
uage, modes of reckoning time and numbers, and
myths and sagas. Finally comes Dr. Virchow's
unt of an Igorroto skull, and a brief vocabulary. It
s portion of the work which renders it one of scien-
nterest, and prevents it from being a mere amusing
unt of the modern grand tour. The numerous
rations which it contains of the tattooing ima-
s, utensils, and the like, add greatly to its value.
Igorrotos are among the disappearing peoples of the
They leave the impression of having once pos-
d a higher culture; their manufactures now are far
those of even half a century ago, and Dr. Meyer
s that, like every primitive race brought into direct
ct with European civilisation, nothing can save them
ultimate extinction.

Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts. No notice is taken of anonymous communications.

Editor urgently requests correspondents to keep their letters as short as possible. The pressure on his space is so great that it is impossible otherwise to insure the appearance even of communications containing interesting and novel facts.]

Molecular Dynamics

THERE must be some mistake in Prof. Forbes' report of Sir Wm. Thomson's remarks as quoted in NATURE of last week (p. 461) upon the rate of wave-propagation on Maxwell's electro-magnetic theory of light. From the end of the last quotation one would suppose that Sir Wm. Thomson intended to convey that the rate of wave-propagation that Maxwell's theory asserted to be the same as that of light, was the rate of propagation of a variation of a current in a conducting wire. Now Sir Wm. Thomson cannot, I am sure, have intended to convey any such mistaken notion. Maxwell carefully guards against any such mistake by pointing out that conduction of electricity is of the nature of diffusion, and not of a wave-propagation, and so has no definite velocity. What Maxwell has calculated is the rate of propagation of disturbances in *non-conductors*, and not in conductors. It is the rate at which the disturbances, produced in the way considered by Sir Wm. Thomson in the preceding part of this quotation, would be propagated by transverse vibrations. Of course, as Sir Wm. Thomson asserts, something analogous to a longitudinal vibration may co-exist with these, but Maxwell's theory shows that a medium which would transmit only transverse vibrations would explain electric and magnetic phenomena.

GEO. FRAS. FITZGERALD.

40, Trinity College, Dublin, March 23

[The passage quoted by Mr. Forbes is correctly reported. A more full explanation of this subject will be found in Nichol's "Cyclopædia," second edition, 1860, article, "Electricity, velocity of;" reprinted in vol. ii., art. lxxxi., of my collected mathematical and physical papers.—W. T.]

Civilisation and Eyesight

HAVING read with much interest the recent correspondence in NATURE on this subject, I am forwarding the results of some observations which I recently made to determine the degree of acuteness of vision possessed by the natives of the islands of Bougainville Straits, in the Solomon Group.

I examined the powers of vision of twenty-two individuals who were in all cases either young adults or of an age not much beyond thirty. For this purpose I employed the square test-dots which are used in examining the sight of recruits for the British army, and I obtained the following results:—Two natives could distinguish the dots clearly at 70 feet, one at 67 feet, two at 65 feet, three at 62 feet, four at 60 feet, two at 55 feet, three at 52 feet, four at 50 feet, and one at 35 feet. The conclusion at which I arrived was that 60 feet represented the average distance at which a native could count the dots—a distance rather greater than that at which they should be placed to test the normal powers of vision, viz. 57 feet.

Of these twenty-two natives I came upon only one whose vision seemed at all defective. In this instance—that of a man about thirty years old—the nature of the cause was sufficiently indicated by the prominence of the eyes and the nipping of the lids, especially when the sight was strained by trying to count the test-dots at a distance. The limit of distance at which the man could count the test-dots was 35 feet. The question which presented itself to my mind in this case was, whether a white man who could count the dots at the same distance—viz. 35 feet—would exhibit to the same degree the external signs of myopia. I might put this query into other words, and ask whether, considering the far-seeing powers of these natives, the peculiar external signs of myopia would not appear with a less degree of this defect than with the white man.

Natives of these islands are very quick at perceiving distant objects, such as ships at sea. I was often much impressed by their facility in picking out pigeons and cassowaries, which were almost concealed in the dense foliage of the trees some 60 or 70 feet overhead. My attention was not attracted by the unusual size of the pupils; the eyes, however, have a soft, fawn-like appearance with but little expression. In conclusion, I may refer to the circumstance that the interiors of their houses are always kept dark, the door being usually the only aperture admitting light. The object is, I believe, to exclude flies and other insects from their dwellings. Coming in from the direct sunlight, I have often had to wait a minute or two before my eyes became accustomed to the change; but the natives do not experience this inconvenience. Some hours of the day they commonly spend in their houses, while at night they use no artificial light except the fitful glare of a wood fire. It would seem probable that the influence of the opposite conditions presented by the bright sunlight and the darkness of their dwellings, would be found in the increased rapidity of the contraction and dilatation of the pupil with the enlargement, perhaps, of the

retinal receiving area. It is, however, a noteworthy circumstance that these natives are able to pass from the bright tropical glare outside their dwellings to the dark interiors, and *vice versâ*, without showing the temporary derangement of vision which the white man experiences whilst the iris is adapting itself to the new condition. H. B. GUPPY

Mr. Lowne on the Morphology of Insects' Eyes

IN reference to the discussion between Dr. Sydney Hickson and Mr. Benjamin Lowne, I beg to state that I have been favoured by both of those gentlemen with opportunities of carefully studying their preparations, and I feel it to be my duty to state that in my judgment Mr. Lowne's preparations do not justify the conclusions which he has based on them, and are, in fact, not made with that skill and knowledge of modern histological method which is necessary in order that trustworthy conclusions may be obtained. On the other hand, Dr. Hickson's preparations are thoroughly satisfactory as examples of histological manipulation. Dr. Hickson supports the accepted view as to the termination of the optic nerve-fibres in the nerve-end cells of the retinulæ. Mr. Lowne denies this connection. I have no doubt that such a connection cannot be readily observed in Mr. Lowne's preparations. At the same time I have no doubt whatever that this is because the preparations are badly made. Mr. Lowne's preparations fail to show many other simple features in the structure of the insect's eye, which are readily seen in preparations made by the application of methods now recognised and approved, but not made use of by Mr. Lowne.

I am sorry to see the resources of the Linnean Society employed in publishing a memoir the conclusions of which, although startling in their novelty, are undeniably based upon the mistaken interpretation of defective preparations.

I think it is important that the Fellows of the Linnean Society should know whether the memoir now published is the same which was read a year or two ago at the Royal Society, and whether the Council of the Royal Society took any steps to ascertain the value of Mr. Lowne's preparations, or came to any decision as to the fitness of Mr. Lowne's paper for publication.

March 14 E. RAY LANKESTER

On the Terminology of the Mathematical Theory of Elasticity

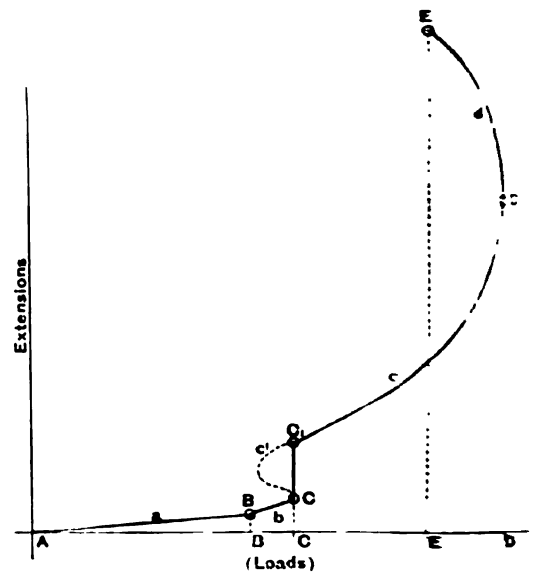
ENGINEERS quite as much as "elasticians" have reason to want some such terminology as that sought by Prof. Pearson (NATURE, vol. xxxi. p. 456), and have equal reason to be indebted to him for undertaking the work which he has at present in hand, which seems already to have given results of practical value as great as their scientific interest.

As I have for some years made a study of the physical side of the problems mentioned by him, I should be glad to make some suggestions as to terminology as contributions to the discussion of the subject in your columns. I will confine what I have to say to what may be called ductile materials (such as wrought iron, ordinary steel, copper, &c.), because in these only the whole phenomena are visible. The behaviour of such material in tension is illustrated by the accompanying figure, in which stresses are measured along the horizontal, and strains along the vertical axis.

It is extremely rare to obtain a piece of raw material already in a *state of ease*. *Wire*, of course, is highly strained by its process of manufacture, but that even ordinary bar and plate is also slightly strained, is shown in the manner mentioned by Prof. Pearson. Such initial strains as become visible as *set* by the first stretching up to any load (within limit of elasticity) disappear after one or two applications of that load. The material is then in a state of ease up to that load, but higher loads (still within the limit), on their first application, generally produce more set—the state of ease thus extending only to the stress employed to produce it. The *sets* are, along with the elastic strain, proportional to the stress, their effect being simply to lower the modulus of elasticity. Probably the process of *annealing* will bring the material into a state of ease for all loads at which such a state is possible. I propose to examine this matter further by [illegible], if possible, of the apparatus described by Prof. D. E. [illegible]hes in the Inst. M. Eng. *Proc.*, 1883, p. 73. In the figure, *a* represents this *condition of perfect elasticity* (maximum ease being presupposed) and B, the superior limit of [illegible] dition, is the mathematical *limit of perfect elasticity*.

After B comes a stage *b*, within which the set is not proportional to the stress, although it still remains small; the extension, therefore, increases faster than the stress. Often this stage does not occur at all, and both its higher and lower limits seem—more than any other points in the material—to be susceptible of change depending on duration. Accidental shock will shorten the stage considerably, gradual loading extends it somewhat. For these and reasons I therefore suggest that this stage be called the *condition of instability*, or of *unstable equilibrium*.

This condition terminates at C, in what I have called "breaking-down" in the paper referred to by Prof. Ewing, which paper I believe the phenomenon was described for the first time. This point is the one called by engineers the limit of elasticity, because it is the only one markedly visible by special apparatus. (The extension at B, on a length of 2 inches, may be about 0·01 inch; at C 0·03 inch and with the same stress, it increases to 0·20, 0·25, and even occasionally 0·4.) If "breaking-down point" be too crude a name, I would suggest *limit of stability*. It should be noted that the [illegible]



point does not remain constant, but in reality appears to rise as the extension goes on, as shown at *c'* (this dotted curve drawn to scale), a matter on which I am at present experimenting. I should add that, during the application of load at any point, extension appears to be occurring at different parts of the length *successively*, and not at all parts simultaneously, as in conditions *a* and *c*.

In the next stage, C to D, the whole strains consist of a small elastic portion (apparently closely following the modulus) and a very large set, increasing much faster than the load. The test bar remains at each load practically constant in cross-section at all points of its length, and rises in temperature instead of (as in condition *a*) cooling. I would suggest for this stage the name *condition of uniform flow*, the physical possibility of which will be obvious to any one who has seen the soft metal in this condition.

At some point, D, a maximum load is reached, and at about the same point (generally, I think, a little earlier, but the difference is small, and not very easy to get at with certainty) the metal begins to flow *locally*, a part becoming much more reduced in cross-section than the rest, and eventually fracture occurs at this place under a less load than D, but with a greater extension as at E. This final stage, *d*, might be called *condition of local flow*. The loads D and E (as Prof. Pearson suggests) were the *maximum* and *terminal* loads respectively). (Their difference was first pointed out, I think, by Mr. Daniel Adamson's experiments (*Journal* I. and S. Inst., 1878). The maximum intensity of the

s always, I think, at F, the cross-section of the bar being rtionately more reduced than the load.

ALEX. B. W. KENNEDY

iversity College, March 23

The Colours of Arctic Animals

E white colour of Arctic mammals and birds has hitherto generally ascribed by evolutionists to protective resem-, the adaptation to a snow-covered country being attri- to the preservation of individuals which by assimilating ir environment in colour, either escaped detection by their or, on the other hand, were by this means enabled to their prey more advantageously. Although a certain t may, in the case of some species, be fairly given to these ic factors, it always appeared to me that this explanation ot in itself sufficient, in face of the consideration that many species so coloured could hardly be said to require such tion on account of persecution, or to derive any obvious tage therefrom for predatory purposes. A more satis- y explanation seemed to be that the mode of coloration in on had, at any rate in the first instance, been brought by natural selection through physical rather than through c agencies. It is well known that white, as the worst ber, is also the worst radiator of all forms of radiant , so that warm-blooded creatures thus clad would be enabled to withstand the severity of an Arctic climate—ss of heat by radiation might, in fact, be expected to be pid than if the hairs or feathers were of a darker colour.[1] ding to a paper recently published by Lord Walsingham,[2] as that this view was entertained as far back as 1846 by ,[3] the only addition to the theory required by modern ion being that we must regard the white covering as having cquired by the ordinary Darwinian process of the survival fittest, *i.e.* by the climatic selection of those individuals tted to withstand the extremely low temperatures of their .

perfectly familiar to zoologists that most animals occasion- ive rise to white varieties, so that the basic variations ary for the establishment of the required modification in lour of the hair and feathers would not have been wanting the gradual approach of the Glacial Epoch. It may be ured whether while may not have been the prevailing among all warm-blooded animals during this period, with ception, perhaps, of those species in which the severity of nate may have been met by an equally effective thickening fur. Certain species which, like the stoat and ptarmigan, e white during winter, may, from this point of view, be ed as reverting seasonally to the mode of coloration which r ancestors was normal during the Glacial Epoch, the re- being in these cases brought about by the same influ- which formerly fixed white as the most advantageous form ering. In accordance with this view, it is sometimes d that the stoat does not commonly turn white during in the south of England, excepting in very severe .* Further observations on this point are much needed.

riking contrast to the white covering of Arctic and Alpine als and birds, it has been found that there is a quite oppo- dency for the insects to become darker and more suffused, elanism being especially noticeable among many of the ptera. Although numerous speculations as to the cause phenomenon have from time to time been advanced, it is aper by Lord Walsingham above referred to that what to be a true cause has for the first time been suggested. thor has, in fact, most ingeniously extended the very nt which had been adduced to account for the white of the mammals and birds to explain the quite opposite m of the insects. According to the present view the anic tendency of northern Lepidoptera must be ascribed natural selection of the darker forms owing to the ad- which these would possess in being able to absorb more olar radiation than their lighter congeners. The same must be regarded as here bringing about opposite effects : ase of warm-blooded animals the loss of heat by radia- etarded by the white covering, whilst in insects, which develop but little heat by respiration, it is of the utmost importance to utilise as much as possible of the solar energy. This will be seen to be all the more necessary when it is considered that, under Arctic conditions, the solar rays have but little power, and that the pairing of the insects has to be effected with great rapidity. In order to test these views experimentally, the author exposed numerous species of Lepidoptera of various colours to the sun's rays on a surface of snow, and observed the rate at which the insects sank beneath the surface. As might have been anticipated, the darker insects, like *Tanagra chaerophyllata*, sank more rapidly than white moths like *Acidalia immutata*, which made but little impression on the snow.

The questions raised by these suggestions and observations certainly appear to be well worthy of consideration when discussing the subject of animal coloration. Thus the explanation of the melanism of Arctic insects now advanced may perhaps, when more fully elaborated, throw further light upon the theory of seasonal dimorphism first proposed by Weismann.[1] If, in accordance with the views of this author, we regard the present winter forms of these seasonally dimorphic Lepidoptera as the ancestral Glacial types, it becomes clear why in such white species as *Pieris napi*, the parent Glacial form *Bryoniæ* should be the darker. In the case of *Arachnia levana* the theory does not at first sight apply, inasmuch as the winter form is lighter than the summer generation (*Prorsa*); here, however, both forms are coloured, and there would be but little difference in their relative heat-absorbing powers. The same remark may apply in the case of our own seasonally dimorphic species of *Selenia* and *Ephyra*.

R. MELDOLA

[1] I may take the present opportunity of pointing out to those who possess the English edition of the "Studies in the Theory of Descent" that an error inadvertently occurs in the numbering of the figures in Plate I. Figs. 2, 3, 4, and 5 should have been numbered respectively 3, 5, 7, and 4. I am indebted to Mr. E. B. Poulton for kindly calling my attention to this transposition.

An Error in Ganot's "Physics"

IN your issue of February 19 (p. 361), E. Douglas Archibald calls attention to a typical error in Ganot's "Physics," 10th edition, p. 325, and assumed that it had run through the ten editions. If he had taken the pains to look back to previous editions the formula would have appeared right, viz. :—

$$P = \frac{0{\cdot}31\ V(H - \frac{1}{2}FE)}{(1 + at)\,760}.$$

In going over the text of earlier issues of the book some minor errors are discoverable, but do not detract materially from the value of the same to the careful student

FRANK E. EMERY,
1st Asst. Sci. Dept.

Mountainville, Orange Co., New York, March 4

WITH reference to the letter of Mr. Frank E. Emery on mine, calling attention to the typical error in Ganot's "Physics," I beg to say that though in some of the earlier editions the error may not exist, it occurs in the 5th and 10th, both of which are in my possession. The inference is very strong that if it occurs in these two it occurs in the editions *intervening*, and thus in HALF of the editions published. The first five editions are now getting out of date, so it is not of much value to people if the error does not exist in them.

I would also observe that if Mr. Emery takes the pains of reading my letter over again he will notice it was explicitly stated to be for the benefit of the large class of students who are *not careful*.

My purpose was in no way to run down Ganot, but to warn people of a pitfall in it.

E. DOUGLAS ARCHIBALD

Tunbridge Wells, March 23

Exceptional Whiteness in Tropical Man

SINGULARLY enough, being encamped in the same place as that from which the paper on "The Blackness of Tropical Man" was written to NATURE some months ago, the converse, a case of the whiteness of this class of man, presented itself unexpectedly. While entering, to-day, the native village of Jeykondashulapurm, that had sunk to nothing from having been the capital of a native dynasty in the south of India, and situated about lat 11° N. and long. 78° E., the writer observed an apparently white woman sitting on a doorstep by the side of the road, with flaxen-coloured

hair, but having in other respects the characteristics of natives attacked by leprosy. Making inquiries from one of the principal native revenue officials at the place, it was ascertained that there was a family living hardly a mile away, of which more than one of the members had been born, and continued, white all their lives. That this did not result from their being lepers, and that none of their neighbours were in the least afraid of them, though opinion was not quite clear as to the whiteness not being disease.

Losing no time, it did not take long to reach the hut in which this family of albinos were to be found. They are of the Hindu blacksmith caste. The father and mother are stated to be of the ordinary blackness of natives of India, but were not seen on this occasion. A son, aged twenty-two, was there working at his trade, with the white colour, features, and light flaxen hair of a European, the only difference being a coarseness of the texture of the skin, and a slightly vacant expression. There was, beside him, an apparently elder brother, quite dark, and a native Hindu in every respect. It was said that albinos had occasionally appeared in the family, one of the uncles, for instance, having been white.

On being questioned as to whether there was any difference between the albinos and ordinary natives, it was at once said that the former could not stand being in the sun, which reddened and inflamed the skin, upon which the remark fell from the writer that it would be worth while to transport such individuals to a cold climate, where they would be exposed to no inconvenience. And so it would, because there can be no doubt that one of these white Hindus, early taken, and educated in a European climate, would from palpable observation of the specimen now described be absolutely indistinguishable as a native of India.

Evidently some cause has interfered with the production of pigment in the cells of the skin, with the effect of rendering the albinos highly sensitive, and more so than a European, to the invisible heat rays of the spectrum, which are so injurious to the constitution in India.

The contrast between the faces of the brothers was peculiarly striking, for there was sufficient resemblance, in the lower part of the face especially, to show there was a distinct relationship—that of the one who was dark wore the ordinary mild composure; but the other, by the mere change of colour, had completely and inadvertently thrown off the Oriental mask; and it would be almost impossible to convey in any one, not seeing it exemplified, how vast a change could be made by so simple an alteration, displaying the way the real individuality of race is lurking in an extraordinary manner beneath a tropical blackness.

India, February 24 A. T. FRASER

Far-sightedness

THOUGH I have already published a note on the subject in a Dutch paper (*Tijdschrift voor het Aardrijkskundig Genootschap*, February, 1883), perhaps you will kindly allow the following lines to have a place in NATURE, because those who are occupied in the trigonometrical survey of British India may take an interest in the matter, and be able to give more particulars about it.

In a paper on Mr. Whymper's travels in Greenland, which appeared in *Svitland*, t. xii., 1884, I found in a foot-note the following remark:—"The reader might be astonished on hearing that I [Mr. Whymper] could see a mountain at such a great distance (about 100 English miles); but I may add that the day before I saw two other mountains 40 and 150 English miles distant; with one exception this was the greatest distance at which I have ever been able to make out objects."

Since I have not found any other reports in which it is expressly stated that objects were seen at a greater distance, I presume I may allege my own experience. While occupied with the trigonometrical survey of Western Java I sometimes had an opportunity of seeing objects at a very great distance, though, under the circumstances I was in, I had no time to look for them on purpose.

The greatest distance at which the angular points of triangles of the first order were from each other was about 105 kilometres; no difficulty ever arose from the distance, and no difference was made whether signals or heliostats (square mirrors of about 3 inches side) were observed.

When on Gog Kazang (Bantam) I made out Kaiserspick (Sumatra) at a distance of more than 110 English miles, though not quite easily, the top just peeping out from the slopes of Selasic; if there had been a signal on Kaiserspick at that time I think I could have observed it.

The greatest distance at which I remember ever to have seen an object was noted during my stay on Gog Tjiboal (Preanger Regentsch), when I made out Gog Merapi (Java) most distinctly at a distance of about 180 English miles,[1] and I suppose that Gog Lawu was also visible (225 English miles distant), but I could not quite distinguish it from the group of mountains of which it is one. It is, of course, from high summits that objects are seen at the greatest distances, and objects which are more elevated at a greater distance than such as are close to the ground.

I think it would be interesting to gather experiences relating to the subject made in different climates and under different circumstances.

Stuttgart, March 23 EMIL MENGA

Krakatoa

SUPPOSING that the underground noises heard at Camorta on Sunday, August 26, 1883, were not only synchronous with but actually the same as, those caused by the great explosion in the Straits of Sunda, it does not seem to follow that the sound-waves were propagated through the whole diameter of the earth. On the contrary, the question is at once raised, at what depth below the surface did the disturbances occur which found an easy and destructive vent at Krakatoa? And if only the time-records north and west were accurate and satisfactory, there would seem to be some datum supplied for approximately estimating this depth. The centre of disturbance may have receded from and become inaudible at the Cumaras in proportion as, on the 27th, a free final vent at Krakatoa.

Bregner, Bournemouth, March 30 HENRY CEE

The Recent Aurora

THE "Sunk" lightship is in electrical communication with the Essex coast, being connected thereto by a telegraphic cable 8·984 nautical miles in length, laid from Walton-on-the-Naze in an easterly direction. The electrical condition of this cable is ascertained daily at 10 a.m., by means of tests applied at the shore ends. Until the 15th inst. these tests were very regular and satisfactory, but on the morning of that day it was found to be impossible to obtain any satisfactory results, owing to electrical disturbances produced in the cable by some external influence. The electrician on board reported that the weather was very fine and summer-like, sea perfectly smooth, with variable light airs, and he could in no way account for the disturbance. the electrician was observing on shore. Between 9 and 10 p.m. those on board the lightship observed in the northern sky a most brilliant aurora, from which at intervals two very bright rays extended upwards to the zenith, and there apparently joined.

I send you these particulars as they may be worth noting in connection with the aurora seen at Christiania on the same evening, and described by Mr. Sophus Tromholt in the last NATURE, published on the 26th inst. (p. 479). There can be no doubt but that the aurora seen at Christiania was identical with that noticed by the men on the lightship off Walton-on-the-Naze, and, although it was not visible until the evening of the 15th, evidently affecting the electrical condition of the earth at the morning of that day, and was the direct cause of the subsequent disturbance in the cable. Since that date the tests have been quite satisfactory and regular as before.

March 30 WILLOUGHBY SMITH

THE COSMOGONIC THEORY OF M. FAYE

M. FAYE has expounded his theoretical views on cosmogony in the several publications mentioned above, and in his book he has also treated of the historical development of cosmogonic theories. We shall in the present article confine our attention to that which is original in his speculation; and we recommend the

[1] In the junction of triangulations of Spelo and Mijang the distance is about 270 kilometres.

planetary systems, and whilst the field is thus left open to the nebular hypothesis or other rival theories, it is submitted that tidal friction has a bearing on those theories which cannot be neglected.

A numerical comparison of the distribution of moment of momentum amongst the several planetary sub-systems shows that the terrestrial system differs considerably from all the others, but it would hardly be logical to postulate an absolutely independent mechanism in this case, and it is not very easy to reconcile the genesis of the moon close to the earth with the formation of a ring in the midst of a planetary agglomeration of meteorites. Let us now summarise the advantages and disadvantages of M. Faye's scheme.

The conception of the growth of planetary bodies by the aggregation of meteorites is a good one, and perhaps seems more probable than the hypothesis that the whole solar system was gaseous, and that the influence of hydrostatic pressure was felt throughout. The internal annulation of the meteorites is left unexplained, and this compares very unfavourably with Laplace's system, where the annulation is the very thing explained. The difference of orbital motion of the inner and outer meteorites of a ring, the development of that difference as time progresses, and the consequence of direct and retrograde rotation at different distances from the sun is an excellent idea. But it is necessary to this idea that the inner planets should have been formed the first, and we are met directly by the fact that the single surviving ring, that of Saturn, is nearer to the planet than are the satellites. It is, of course, possible that special causes have preserved this ring, but we should be driven to the startling conclusion that Saturn's ring is the oldest feature of his system.

The actual distribution of satellites in the solar system is at variance with M. Faye's theory, for, according to him, the internal planets were generated from rings whose motion was such as would give greater moment of momentum to the planetary agglomeration than would the external ones. The number of satellites manufactured should be greater the greater the amount of rotation in the primitive agglomeration of meteorites, and thus the nearer planets should be richer in satellites than the remote ones.

The celebrated experiment of Plateau, in which a drop of oil rotating in alcohol and water is made to parody Laplace's solar system, is worthy of attention, and it tells against Faye and in favour of Laplace. It is of course to be admitted that surface-tension does not duly represent gravity.

On the whole, then, we must hold the opinion that there are great difficulties in the acceptance of M. Faye's theory, notwithstanding its excellences. The time does not appear yet ripe for definite judgment on this very complex subject, but science is undoubtedly the gainer by such suggestive theories. Whilst a false statement of fact always proves a serious detriment, the enunciation of false or partially true theories is always the incentive to, or initiation of, the discovery of truth.

G. H. Darwin

SIR WILLIAM THOMSON ON MOLECULAR DYNAMICS[1]

II.

IN the present article Sir William Thomson's spring and shell molecule will be described and its theory sketched, in so far as this has been investigated with the view of getting over some of the difficulties which surround the wave theory of light. In Helmholtz's memoir on anomalous dispersion, a sketch of such a theory was published. But this new molecule differs from that of Helmholtz in several points, chiefly in the fact that absorption is not accounted for by any viscous action in the molecule dissipating the energy of vibration into low-grade heat. Most readers who have ever visited the natural philosophy lecture-room in Glasgow University will recognise a very old friend in this new molecule where they have seen it vibrating, I suppose, any time since the University occupied its present site. In appearance the molecule has been changed, but its theory as taught to the students there is identical. For a description of this molecule let us refer to page 10 of the lectures:—

"Imagine for a moment that we make a rude mechanical model. Let this be an infinitely rigid spherical shell; let there be another absolutely rigid shell inside of that, and so on, as many as you please. Naturally we might think of something more continuous than that, but I only wish to call attention to a crude mechanical explanation, possibly of the effects of dispersion. Suppose we had luminiferous ether outside, and that this hollow space is of very small diameter in comparison with the wave-length. Let zig-zag springs connect the outer rigid boundary with boundary number two. I use a zig-zag, not a spiral, spring which has the helical properties which we are not ready for yet, such properties as sugar and quartz have in disturbing the luminiferous vibrations. Suppose we have shells two and three also connected by a sufficient number of spiral springs, and so on; and let there be a solid inclosed in the centre with spiral connections between it and the shell outside of it. If there is only one of these interior shells, you will have no definite period of vibration. Suppose you take away everything except that one interior shell; displace the shell and let it vibrate. The period of its vibration is perfectly definite. If you have an immense number of such shells with moveable molecules inside of them distributed through some portion of the luminiferous ether you will put it into a condition in which the velocity of propagation of the wave will be different from what it is in the homogeneous luminiferous ether. You have one is called for, viz. a definite period; and the relation between the period of vibration in the light considered and the period of the free vibration of the shell will be fundamental in respect to the attempt of a modelmaker to that kind to represent the phenomena of dispersion.

"If you take away everything except the one shell, you will have almost exactly, I think, the view of Helmholtz's paper—a crude model as it were of what Helmholtz makes his paper on anomalous dispersion. Helmholtz besides that, supposes a certain degree or coefficient of viscous resistance against the vibration of the inner shell relatively to the outer one. Helmholtz does not reduce to a gross mechanical form like this, but merely assumes particles connected with the luminiferous ether and assumes a viscous motion to operate against the motion of the particles."

In the lectures the action of such a molecule when subjected to forced vibrations was illustrated by a model of ingenious construction, which among the students passed by the name of the "wiggler." A steel wire was hung vertically, and five or six lathes 2 feet long and 2 inches wide were attached in a horizontal position to the wire, each one having three pins fixed in it for the purpose. These lathes were loaded at their ends, the weight on each lathe being less than that on the one above it. The lowest lathe was attached to a pendulum arrangement which impressed forced vibrations upon the system, the period being adjustable. The theory of such a system is the same as that of the molecule described above.

But in working out the theory a third type of molecule was used, the identical one which vibrates in the lecture-room at Glasgow. This is a series of weights attached to each other by vertical springs which can be represented. The highest is the heaviest, and the others are arranged in the order of weight.

[1] Continued from p. 486.

Calling P the lathe with forced vibrations (corresponding to the external massless shell acted on by the ether), and ξ its displacement, m_0, m_1, &c., are the successive masses, x_0, x_1, &c., are their displacements

$$u_2 = -\frac{c_2 x_1}{x_2},$$

and measures the relative displacement of m_1 and m_2. c_1, c_2, &c., are the constants of successive spring connections. $c_2(x_1 - x_2)$ is the force of restitution in virtue of the spring connection between x_1 and x_2. τ is the period of forced vibration.

We thus arrive at the equation

$$\frac{du_i}{d\tau} = -\frac{2}{\tau^3} \cdot \frac{1}{x_i^2}(m_i x_i^2 + m_{i+1} x_{i+1}^2 + \ldots + m_j x_j^2),$$

and since the right hand member is essentially negative, it follows that all the u's diminish with increase of period. The critical cases occur when the period of forced vibration agrees with the natural period of any of the shells or lathes. When the forced vibration is very rapid, all successive masses move in opposite directions. When the forced period is slower, u_1 becomes zero, and x_1 is infinite—*i.e.* the vibration of the lowest mass is infinite in comparison with the forced vibrator, and so with the other vibrators. When the forced period is slower, u^1 becomes negative, *i.e.* the lowest mass begins to vibrate in the same direction, as the forced vibrator. Successive critical cases occur as the forced period reaches the natural periods of successive vibrators. At the critical period for any one vibrator, all those below it are vibrating in one direction, while the critical one and those above it are executing very large vibrations in opposite directions successively.

These critical periods are admirably adapted for explaining absorption and also anomalous dispersion. In highly absorbing media which cut off a band of light from the spectrum, the refractive index for colours neighbouring to the band is remarkable; thus light of greater wave-length than the band is refracted more, and light of less wave-length than the band is refracted less than in normal substances. Lord Rayleigh considered this to be due to the mutual influence of the vibrating molecule and ether. If the point of support of a pendulum is vibrated in a different period, the period of the pendulum is changed. Lommel seems to have been the first to make dispersion depend upon associated matter.

The influence of a large number of the spring and shell molecules distributed through the ether upon the velocity of light in that medium is examined and shown to depend upon the wave-length or period. Finally at p. 108 we obtain the following formula:—

$$\frac{\tau^2}{\lambda^2} = \frac{1}{l}\left[\rho - c_1\tau^2\left\{1 + \frac{c_1\tau^2}{m_1}\left(\frac{\kappa_1^2 R_1}{\kappa_1^2 - \tau^2} + \frac{\kappa_2^2 R_2}{\kappa_2^2 - \tau^2} + \ldots\right)\right\}\right].$$

ρ and l measure the density and rigidity.

$R_i = \dfrac{\text{Energy of } i\text{th shell}}{\text{Energy of the whole}}$.

κ_i = the ith critical period.

"This is the expression for the square of the refractive index, as it is affected by the presence of molecules arranged in that way. It is too late to go into this for interpretation just now, but I will tell you that if you take τ considerably less than κ_1 and very much greater than κ_2 you will get a formula with enough disposable constants to represent the index of refraction by an empirical formula, as it were, which from what we know, and from what Sellmeier and Ketteler have shown, we can accept as ample for representing the refraction index of most transparent substances. We have the means of extruding its powers and introducing the effects of those other terms, so that we have a formula which is more than sufficient to give us a mathematical expression of the refrangibility in the case of any transparent body whose refrangibility is reliable."

In fact the above formula is equivalent to the well-known formula of Cauchy and others, viz.

$$\mu = \mu_0\left(A + \frac{B}{\lambda^2} + \frac{C}{\lambda^4} + \ldots\right)$$

when we are not dealing with critical cases. Examining the formula for $\frac{\tau^2}{\lambda^2}$ or μ^2, we see that as τ approaches κ_1, μ^2 becomes infinite, and for τ a little greater than κ_1, μ^2 is negative, which is impossible, and we can have no assignable velocity for such a period—*i.e.* there is absorption for all values of $\tau > \kappa_1$, which make μ^2 negative. Moreover, owing to the existence of a critical period, κ_1, the refractive index is abnormally increased for values of τ which are just less than κ_1, and it is abnormally diminished just when μ^2 becomes positive. This means that the refrangibility of rays in a highly absorbent medium, in the neighbourhood of the band of absorption, is anomalous in the direction indicated by Kundt in his researches on anomalous dispersion. Here is what we find at p. 150 on critical values of τ and the manner of absorption:—

"We shall try to see something more of the effect of light propagated through a medium of a period exactly equal K_1. I believe each sequence of vibrations will throw in a little energy which will spread out among the different possible motions of the molecule. The combination of the sequences, forming what we call continuous light, is not a continuous phenomenon at all. I believe that the first effect when light begins will be: each sequence of waves of the exact period throws in some energy into the molecule. That goes on until, somewhere or other, the molecule gets uneasy. It takes in an enormous amount of energy before it begins to get particularly uneasy. It then moves about, and begins to collide with its neighbours perhaps, and will therefore give you heat in the gas, if it be a gaseous molecule. It goes on colliding with the other molecules, and in that way imparting its energy to them. The energy will be simply carried away, by convection if you please, or a part of it perhaps. Each molecule set to vibrating in that way becomes a source of light, and so we may explain the radiation of heat from the molecule after it has been got into the molecule by sequences of waves of light. I believe we can so explain the augmented pressure of a gas due to the absorption of heat in it.

"We may consider, however, that the chiefest vibration of the molecule is that in which the nucleus goes in one direction, and the shell in the opposite direction, but with a great amount of energy in the interior vibrations and very little in the shell, so that the shell may go on giving out phosphorescent energy for two or three hours or days, simply vibrating for ever, except in so far as the energy is drawn off and allowed to give motion to other bodies."

A great deal more is said about the influence of critical periods upon anomalous dispersion, but, as the author says, "it is like fiddling when Rome is burning to discuss anomalous dispersion when double refraction is waiting to be explained," so I will pass from this subject.

We have in the lectures some indications of the effect of introducing a gyrostat inside the shell molecule, especially with relation to magnetic rotation of the plane of polarisation. On this subject the author said sadly: "But alas! my results give me another law, not more effect with greater frequency, but less effect with greater frequency, according to the inverse square of the wave-length. I therefore lay it aside for the present, but with perfect faith that the principle of explanation of the thing is there" (p. 244).

But, on returning to this country, a more complete theory of the gyrostatic molecule was worked out, sent to

America, and incorporated in the lectures. In my next and concluding notice I shall touch on the further developments if space permits.[1]

GEORGE FORBES

(*To be continued.*)

CITY AND GUILDS OF LONDON INSTITUTE

THE Fifth Annual Report of the Council of this Institute, which was presented last week to the Governors by the Lord Chancellor, gives evidence of marked progress in all departments of the Institute's operations. During the last five years, the advance made in this country in providing technical schools of various grades has been very great, and brings us educationally within a measurable distance of France and Germany. Much praise is certainly due to the City Companies for the very energetic manner in which they have set about giving effect to the important objects they have undertaken. The Technical College at Finsbury and the Central Institution at South Kensington are important additions to the educational establishments of the metropolis. That the Finsbury College has supplied a great want is shown by the rapid increase in the number of students during the two years since it was opened. The number of evening students might have been expected to be large, because in very few places, if in any, do evening students have the same advantages as at Finsbury of obtaining practical instruction in physics and mechanics. But the great success of the College is shown in the increasing number of its day students. In little more than two years the number has increased from 30 to 148; and nearly all these students are in regular attendance throughout the whole day, and go through the complete course of instruction as laid down for them in the programme. Some changes have taken place in the staff of the College in consequence of the opening of the Central Institution. Mr. Philip Magnus has been relieved of the duties of Principal, which he temporarily undertook in addition to his other duties as organising Director of the Institute, and Profs. Ayrton and Armstrong have resigned the Chairs of Physics and Chemistry for similar positions at the Central Institution. The appointment of Dr. Silvanus Thompson as Principal and Professor of Physics at Finsbury promises well for the future of the College, and the Council have been well advised in this selection. The Professorship of Chemistry is still vacant.

The Central Institution, which is to form a kind of technical university, was formally opened in June last, but, as generally happens, the completion of the fittings has occupied more time than was anticipated, and the Institution is consequently not yet in working order. The Prince of Wales, who has shown great interest in the progress of the Institute, issued an appeal to the Lord Mayor and to the Masters of the several Companies for additional funds to defray the cost of the fittings, which brought in over 17,000*l*. It may be expected, therefore, that this Central College will be very completely furnished with all the necessary appliances and apparatus for scientific and technical instruction.

The Council of the Institute refer with satisfaction to several passages in the Report of the Royal Commissioners on Technical Instruction, showing the great need in this country of improved facilities for higher technical teaching. It is a common error, which the building in South Kensington will help to correct, that technical education has reference to artisans only, and that the improvement of the skill of the working man is the great *desideratum* in the commercial interests of the country. But this is not so. The difference between foreign countries and our own in the facilities afforded for the education of artisans is not so marked as in the opportunities for the higher education of masters and managers of works.

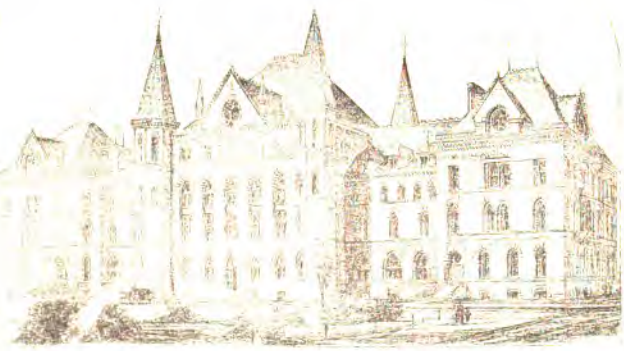
But the City Guilds Institute, whilst giving promise in its scheme to the provision of this higher education in its Central Institution, has done a great work in assisting in the establishment of evening technical schools in the principal manufacturing centres of the kingdom by means of its system of technological examinations. The Director's special Report on this part of the Institute's work is full of detailed information as to the increase in the number of candidates and of subjects of examination, and is supplemented by remarks of the examiners on the causes of the failures of the candidates. The percentage of failures is decidedly high; but the Institute very wisely insists upon a high standard of excellence, as the value of certificates may be accepted by masters and workmen as proof of the efficiency of those who hold them. As many crafts, this would be impossible, if the certificates were awarded on the results of a written examination only, but the practical tests which have this year been introduced afford a guarantee, which would otherwise be wanting, for the technical skill, as well as of the knowledge of the candidates. In the examination in "weaving," for instance, the candidate is required to design an original pattern, and to prepare it for the loom, and to weave it in suitable material, besides answering questions on the weaving of various patterns, the structure of the different kinds of looms, &c. In mine surveying, also, a practical examination was for the year held at the Pease's West Collieries, in which the candidates were engaged, with the examiner, in surface and underground work during the three days. With the Institute's examinations are thus conducted there can be no doubt of their efficiency, and of their affording a valuable supplement to those of the Science and Art Department. Most of the Institute's examiners complain of the candidates' want of skill in drawing, and it is satisfactory to note that the attention of the Education Department has been called to this general defect in the education given in our primary schools, and that it is likely to be remedied by the provisions for teaching elementary drawing throughout the Standards contained in the new Code for 1885.

The Report of the Institute concludes with an appeal for additional funds. If the Council are to develop its work they have begun they require a much larger income than they now dispense. A good beginning has been made, but it is little more than a beginning, in the establishment of technical schools in this country. Leeds, Nottingham, Sheffield, and Manchester have received some assistance from the Institute; but there are many manufacturing towns still requiring help, and the wants of the metropolis are by no means satisfied. It is to be hoped, therefore, that the appeal of the Council, backed by the powerful support of the Lord Chancellor, will meet with a ready and adequate response.

THE PEABODY MUSEUM AT NEW HAVEN, U.S.

THE accompanying illustration of this fine museum is reproduced from *Science*. The Peabody Museum, Mr. Ingersoll informs us, stands on the corner of Elm and High Streets, just without the *campus* of Yale College. The building is due to the liberality of George Peabody, who gave a sum of money, in 1866, to erect a house for the collections. Thanks to the financial prosperity of Massachusetts, the funds for a hundred and fifty thousand dollars had greatly increased, and when set aside for the first wing of the building had become worth a hundred and seventy-five thousand dollars when the trustees began to build. With that sum they have erected one of the finest buildings, for its purpose, in the United States—a lofty and ornamental structure of red brick with cream-coloured stone, whose broad and numerous windows

[1] Corrections to first notice in issue of March 19:—For *asphaeia* read *aphasia*. P. 462, line 41 of second column, *for a few seconds*, read *for a few thousandths of a second*. P. 463, line 33 of first column, for *without* read *with*.



They are confined almost wholly, however, to the cases of tanks, mollusks, radiates, and marine protozoa. Of insects there is a very small show-case only enough to represent scantily the classification of that immense class. This is partly because it is almost impossible to display insects freely, since exposure to the light causes their colours to fade, but is due chiefly to lack of material, owing to the fact that no entomologists of note have been especially interested in the progress of this museum.

On the other hand, the special cases of Lieut. Verrill, S. I. Smith, J. H. Emerton, and others, and the magnificent alcohol series of Museum duplicates, kept on hand in connection with the Smithsonian Institution and the U. S. Fish Commission, have brought the department of marine invertebrates to an almost unrivalled performance. In no room does the crowding of longer hours mean so much as in one which its contents are mostly safely preserved in alcohol, because of the huge proportion of type specimens included. In many instances—those are unique, as for example, some of these beautiful sponges and starfish, zoophytes or "sea-pinks," Portuguese men-of-war, and other gelatinous or "sea-blubber" forms, which, less moist, crumble at a touch, and even unique forms, as might be expected, remarkably fine, including Prof. J. D. Dana's illustrations of his classification of crustaceans, only the Museum of Comparative Zoology equals this part of the exhibit.

In the way of deepest loans of type specimens, Prof. Alexander Agassiz, also a great patron of many museums, has publicly displayed, as he well may proud as to the privilege, in the Fish Commission Annex, the wonderful collection of echinoderms, or sea-urchins, and their allies, upon which Verrill has worked so many years, and which is the largest and most perfect thing of the kind in existence, containing several thousand species, which but few museums in the world have even a single example of, and which, it is said, it would be well nigh impossible to duplicate in a lifetime. Prof. Agassiz has also loaned a large collection of fossil echinoderms

question force itself upon us, What of this power which reads and interprets nature? Beside and beyond the outward and visible, linked to it by mysterious connection, is the sphere of thought, of mind, the home and dwelling-place of thought. What is this being of ours which thinks, plans, and wills? What means it? Whither tends it? This, the question of questions, from far distant periods, souls possessed with profound genius have dared to ask and yearned for a reply. When no complete reply was gained, they yet toiled on, finding in the search food for deeper and more reverent wonder than even in the splendid picture which outward nature displays. They held fast the courageous and hopeful faith that for man who 'names the name Eternity,' 'there must be answer,' here or elsewhere to his trembling doubt, to his 'obstinate questionings.' Such searchers were the early Greek philosophers, who kindled a spark amid surrounding darkness, destined not to die out, but gradually to brighten by careful tendance, and grow into a light that will shine to all coming times, as successive generations of inquiring spirits look up to the great names of Plato and Aristotle as loftiest among their guides and forerunners. In the unsurpassed lucidity of diction exhibited by these two masters, we are led into the very foundry of ideas, and can follow the subtle process of new-born thought growing clearer to itself, and shaping language into its close-fitting outward vesture."

THE Queen has intimated through Sir Henry Ponsonby that she will contribute 50*l.* to the guarantee fund in connection with the approaching visit of the British Association to Aberdeen. The fund is now almost completed. We learn that the nomination as President of the British Association at the Birmingham meeting in 1886 has been offered to Sir William Dawson, C.M.G., LL.D., F.R.S., principal of McGill College, Montreal, and that he has telegraphed his intention of accepting the honour.

AN important meeting was held on Monday at Marlborough House, under the presidency of the Prince of Wales, in connection with the Colonial and Indian Exhibition of 1886. The Prince of Wales, in an address of some length, stated the objects of the Exhibition, which is likely to form one of the most attractive and instructive of any recently held at South Kensington. As the Prince stated, the objects for which her Majesty has been pleased to appoint this Commission are, briefly, to organise and carry out an exhibition by which the reproductive resources of our colonies and of the Indian Empire may be brought before the people of Great Britain, and by which also the distant portions of her Majesty's dominions may be enabled to compare the advances made by each other in trade, manufactures, and general material progress. No such opportunity of becoming practically acquainted with the economic condition of our colonies and the Indian Empire has ever been afforded in this country. A guarantee fund of 128,000*l.* has already been secured, though it is not likely that any of this will be required.

THE following are the Royal Institution lecture arrangements after Easter:—Prof. Gamgee, eight lectures on digestion and nutrition, on Tuesdays, April 14 to June 2; Prof. Tyndall, five lectures on natural forces and energies, on Thursdays, April 16 to May 14; Prof. Meymott Tidy, three lectures on poisons in relation to their chemical constitution and to vital functions, on Thursdays, May 21, 28, June 4; Mr. W. Carruthers, four lectures on fir-trees and their allies, in the present and in the past, on Saturdays, April 18 to May 9; Prof. Odling, two lectures on organic septics and antiseptics, on Saturdays, May 16, 23; and Rev. C. Taylor, two lectures on a lately discovered document, possibly of the first century, entitled "The Teaching of the Twelve Apostles," with illustrations from the Talmud. The Friday evening meetings will be resumed on April 17, when Prof. S. P. Langley, of the Alleghany Observatory, Pennsylvania, will give a discourse on sunlight and the earth's atmosphere.

ON March 25 the Sunday Society held a National Conference at St. James's Hall with the authorities and officers of museums, art galleries, and libraries which have been open in the United Kingdom on Sundays. There was a good attendance, those present for the most part being representative men; a large number of ladies were present. Prof. Corfield, the Chairman of the Committee, presided. The chairman having briefly opened the proceedings, official statements respecting the Sunday opening of the following institutions, which are supported by public money, were submitted by different speakers:—National Museum and Exhibition of Pictures at Kew; National Picture Galleries at Hampton Court Palace; National Picture Gallery at Greenwich Hospital; National Gallery, Dublin; National Museum of Science and Art, Dublin; Birmingham Art Gallery and Library; Manchester—six Free Public Libraries; Middlesborough Free Public Library; Newcastle-upon-Tyne Free Public Library; Stockport Museum; Stoke-upon-Trent Free Library and Museum; Wigan Free Public Library. Each of these official statements spoke of satisfactory results as the outcome of Sunday opening, the statements by Mr. Valentine Ball, F.R.S., Director of the Dublin Science and Art Museum; Mr. Caddie, Principal Librarian and Curator of the Library and Museum in Stoke-upon-Trent, and by Major Turner, Chairman of the Stockport Library and Museum, being specially exhaustive and interesting. The Rev. Septimus Hansard, M.A., rector of Bethnal Green, proposed the following resolution:—"That the facts submitted to this Conference respecting those public museums, art galleries, and libraries which have been opened on Sundays in the United Kingdom are most satisfactory, and it is hereby resolved that they be embodied in petitions to be presented to the Lords of the Treasury and the House of Commons, praying that the trustees of the British Museum and the National Gallery may be provided with the money required to enable them to open these institutions on Sunday afternoons." This was seconded by Mr. John Westlake, Q.C., LL.D., and supported by a great many speakers, including Mr. Wyles, of Coventry; Mr. Freak, of the National Boot and Shoe Riveters' Society; Mr. Steele, J.P., of Rochester; Mr. Faulkner, M.A., of Oxford; Mr. R. M. Morrell, Mr. H. Rutherford, and Mr. Mark H. Judge. The resolution was carried unanimously.

MR. THOMAS FLETCHER, of Warrington, gave a useful lecture on "Smokeless Houses and Manufactories" at the Parkes Museum on March 26. In concluding his lecture, Mr. Fletcher said:—"The ground has been cleared by independent experimenters, and I think it may fairly be said that both houses and all manufacturing industries can be profitably carried on absolutely without smoke, and it is simply a question of time as to when this state of things becomes general throughout the world. Some people are afraid that when after a short time the coal supply of England is exhausted, the predicted New Zealander, when he sits on the ruins of Westminster Abbey, will be able to live on the rabbits caught amongst the ruins; but if gaseous fuel is adopted in our houses and flameless regenerative furnaces are used in our manufactories it is probable that the coming New Zealander will have to defer his visit for a length of time which the present generation need not consider; in fact, we shall be able to import our fuel from unexhausted countries, and hold our own against them after our coal is all gone. The future of gaseous fuel is settled beyond all question on the best of all possible grounds, that it is profitable to use, and users of solid fuel will soon discontinue their present system when they learn their position in the matter."

FROM a letter addressed by the Rev. Edward Reynolds, of Rowland, Limestone County, Alabama, United States, dated September 23, 1884, to the Krakatoa Committee of the Royal Society, we take the following extract:—"Soon after becoming acquainted with the zodiacal light, I began to notice red sunsets. After a few years I noticed that they invariably followed the commencement of the zodiacal light, and continued about the same length of time—that is, about two or three months. I seldom failed to call the attention of my friends and neighbours to these phenomena. Until this last display of the zodiacal light, and its invariable attendants, the red sunrises and sunsets, I have always accounted for the redness by supposing it to be caused by the oblique passage of the sun's rays through his nebular train. But this season I have been obliged to give up that theory, because the redness has continued after the disappearance of the zodiacal light. It is now more than ten months since their commencement, about November 13. They still continue to show no signs of abatement, but rather increase in vividness. Hence, I infer that the immediate cause of the redness is within the atmosphere, rather than in the distant and invisible nebulous train of the sun. We have not this season had a single day nor hour of clear, blue sky, such as is common in ordinary years. We have had plenty of *cumulus* days, but none of the pure blue. There is a yellowish, creamy whiteness, especially far and wide about the sun, even at midday. In looking across a forty-acre lot there is, at all times of the day, a peculiar blueness in the atmosphere, whilst at night not more than a third or half of the stars can be seen. The freer from clouds the heavens are, the more distinctly do the red sunrises and sunsets appear; and so of the other appearances of the atmosphere I have mentioned. During the evenings following November 13 last I was able to see the zodiacal light but a few times, and then very indistinctly. I watched long for an opportunity to show it to my friends and neighbours, but failed to find an evening when it could be seen by unpractised eyes. It has never been so before, since my attention was called to this subject forty-four years ago."

THE following account, we learn from *Science*, of unusual phenomena was received, March 10, at the Hydrographic Office, Washington, from the branch office in San Francisco. The barque *Isaac Wright*, Capt. Waters, has just arrived at Victoria from Yokohama. At midnight of February 24, in latitude 37° north, longitude 170° 15′ east, the captain was aroused by the mate, and went on deck to find the sky changing to a fiery red. All at once a large mass of fire appeared over the vessel, completely blinding the spectators; and, as it fell into the sea some fifty yards to leeward, it caused a hissing sound, which was heard above the blast, and made the vessel quiver from stem to stern. Hardly had this disappeared, when a lowering mass of white foam was seen rapidly approaching the vessel. The noise from the advancing volume of water is described as deafening. The barque was struck flat aback; but, before there was time to touch a brace, the sails had filled again, and the roaring white sea had passed ahead. To increase the horror of the situation, another "vast sheet of flame" ran down the mizen mast, and "poured in myriads of sparks" from the rigging. The strange redness of the sky remained for twenty minutes. The master, an old and experienced mariner, declares that the awfulness of the sight was beyond description, and considers that the ship had a narrow escape from destruction.

THE United States Bureau of Education have printed and distributed an address, by the Rev. A. D. Mayo, on the subject of education in the South, which, balloon-like, may raise some heavy hearts by its very inflation! He urges the folly of casting upon the ignorant mass of either race the responsibility of educating itself, and he tries to rouse enthusiasm like his own among Southerners who are educated; urging the first call upon local taxes to which education is entitled; the necessity of whatever effort which may be made by both males and females, to appreciate his views and will qualify themselves for leading and the small importance of buildings, books, or apparatus where a school has been commenced from the "soul out," a good teacher.

IT is unquestionable now that the new trigonometrical survey which has been made in the Netherlands (especially by the late Mr. Stamkart) for the European Commission since 1861 is not sufficient for the purpose for which it was undertaken, and a second chamber of the "Staten Generaal" has lately voted the money required for doing the work over again. Strange to say, it was the Minister himself who objected to this work, and that as long as Mr. Stamkart lived, his colleagues (the Dutch deputies to the European Commission) had made no objection to his work, and consequently he feared that perhaps later it might be said that the survey now proposed would also have to be done over again. Though it is to be regretted that such is the case, we cannot wonder at the Dutch Government objecting to such an expense, after its experience both in the Netherlands and in the Dutch East Indies.

THERE is a curious analogy in China to the English custom of burying suicides at cross-roads, with a stake through the body. The body of the *felo de se* who is so irreverent as to commit self-destruction within the precincts of that portion of Peking in which the Imperial Court is situated, is usually brought to some public place, such as a bridge, and there flogged.

THE inaugural address of the President of the Leicester Literary and Philosophical Society on the jubilee of the Society, which has been published separately (Leicester: Clarke and Hodgson) is characterised by a circumstance which is probably unprecedented in the history of societies. The President for the year is Dr. George Shaw, who was also the President, and who delivered the first address to the Society fifty years ago. That the same President of a society at its formation and at its fiftieth anniversary is a coincidence of peculiar interest. Dr. Shaw is naturally retrospective, for he describes the labours of the founders, and the progress which has been made in the half century. The little pamphlet should be of use to all interested in steering young societies through the rocks and shallows which beset all enterprises in the earlier stages of their existence. In the case of the Leicester Society the stages were: (1) the period were too dry and abstruse, and no one attended—leaving the infant suffocating the infant; (2) they became popular, but philosophical, and more literary, to the detriment of severe study—the infant's constitution was being destroyed by pernicious ration, and their presence was indicative of a want of study amongst its members. After his biography of the Society Dr. Shaw discusses the spirit of the present age, and the success of the Leicester Philosophical and Literary Society, which is congratulated if their presidential address fifty years hence is anything like so vigorous, encouraging, and abreast of the times that on their jubilee.

MR. ADAM SEDGWICK has in preparation a new book, which is entitled "The Elements of Animal Biology," which is intended to serve as an introduction to the study of animal morphology and physiology. Messrs. Swan Sonnenschein and Co. are the publishers.

DR. BULLER, of Wellington, New Zealand, is preparing for the press a new and enlarged edition of his "History of the Birds of New Zealand." The "history" will comprise a general introduction on the ornithology of New Zealand, and a concise diagnosis of each bird in Latin and English, synoptical ta

On April 9 at 3h. 48m. there is a near approach of 14 Capricorni to the Moon at 339° from the vertex to right, for inverted image.

April 8, 2h.—Mercury at greatest elongation from the Sun, 19° East.

GEOGRAPHICAL NOTES

A COMMITTEE of the Geographical Society of Vienna has been appointed to carry out the business arrangements of Prof. Lenz's proposed expedition to Central Africa. It is reckoned that 25,000fl. will be wanted for the expedition. At first it was thought that Herr Lenz might go out as the representative of the united Geographical Societies of Vienna, Berlin, and Munich, but the Society of Berlin has decided to send out an explorer of its own, Dr. Fischer, who will start next month. Dr. Fischer will go for the same purpose as Herr Lenz—that is, to explore the watershed of the Upper Congo, and to find traces of the four missing Europeans. But instead of starting from the west coast, as Dr. Lenz proposes to do, he will proceed from the east coast, going from Zanzibar to Uganda.

THE fifth German Geographical Congress (*Geographentag*) will be held in Hamburg on April 9 to 12. Among the points which will be brought before the Congress are the following: Antarctic investigations by Drs. Neumayer and Ratzel; the importance of the Panama Canal to the trade of the world, and deliberations on a new edition of Dr. Neumayer's "Guide to Scientific Observations on Travel." The afternoons will, as hitherto, be devoted to questions connected with school geography. The exhibition directed by Prof. Pagenstecher promises to be especially interesting and exhaustive. It is intended to exhibit new maps, especially in the domain of hydrography, and all the maps and descriptions of the free town of Hamburg and the adjoining districts. The instruments and apparatus used by travellers will be collected in a single group. Rich public and private collections of African and Central American ethnographical and archæological objects will be exhibited, and in part explained by their owners. An exhibit of the produces and articles of trade of the various colonies has been rendered possible by the co-operation of large mercantile firms in Hamburg; and zoological, botanical, and geological collections will be so grouped that the character of single countries and continents will readily strike the eye. Some excursions will also be made, especially one to the marshes of the lower Elbe.

WE have received a reprint of a paper recently read before the Philosophical Society of Glasgow by the Rev. Alexander Williamson, the well-known traveller in North China. In the compass of thirty octavo pages the writer describes rapidly the extent, physical conformation, means of intercommunication (especially the rivers, the enormous importance of which is pointed out with much force), the nature of the soil and its products, meteorology, textile fabrics, oil-producing plants, dyes, the geology, trade routes, the race, population, and finally discusses the future. The portions of the subject to which Dr. Williamson devotes especial attention are precisely those which are wholly passed over, or only lightly glanced at in popular works in China. The section dealing with the geology of China gives some remarkable results, based on the investigations of Pumpelly and Richthofen. These show that under every one of the eighteen provinces of China, each of which is about as large as Great Britain, there are large deposits of coal. In some provinces it underlies the whole country in all descriptions—bituminous, anthracite, cannel, and lignite. The extent of these coal-measures may be gathered from the following statement:—Their total area is about 400,000 square miles in China proper. The coal-field in Hunan alone is greater than the aggregate of the coal-fields of the [illegible] countries in Europe; the Shansi coal-field [illegible] times larger than this aggregate, while in other parts of China we have coal-fields seven times greater than all the districts in Great Britain. And, side by side with all the coal-fields investigated, Mr. Pumpelly found iron ores and [illegible] of all descriptions. As regards the important geographical and commercial questions involved in trade-routes with South-Western China, Dr. Williamson is in favour of the route by Moulmein through the Shan States, crossing the Chinese frontier into Yunnan at Ssu-mao (Esmok); but he does not despise the road by the Irrawaddy to Bahmo, and so by Tali-fu to Yang-tse, more especially as the latter would create a trade itself—viz. that with Sse-chian. Then there is the ancient route between Central Asia and China, which passes through Hami, Shensi, and Kansu, the southern branch of which leads through Yarkand, Kashgar, and Khoten to India and Persia, and which was used by caravans prior to the Christian era, while the other branch goes in a north-westerly direction to Bar-kul, Issik-kul, and thence to Russian territory.

MR. STANFORD, of Charing Cross, has published a Catalogue of Maps, and other geographical publications, calculated to be of great service to all who may have occasion to inquire about such things. The catalogue covers seventy-two pages, is carefully classified, beginning with maps of the world; after the list of each map is an account of its special features, its size, scale of sheets, scale in miles to an inch, and price, according to method of doing up. The Catalogue, we may say, contains the maps of all the leading publishers in Europe. As Mr. Stanford is now sole agent for the Ordnance Survey Maps, a [illegible] section of the Catalogue is devoted to this department, and contains a very useful index map.

MESSRS. W. AND A. K. JOHNSTON have also sent us a copy of their new catalogue of the many geographical and other works published by that well-known firm. We have also [illegible] same firm a very excellent wall-map of Egypt, embracing the country down to the south of Lake Victoria Nyanza, and brought so well up to date as to contain the leading features of Masai Land discovered by Mr. Joseph Thomson's last expedition. Accompanying the map is a useful Handbook to the Geography of Egypt.

THE Arctic ship *Alert*, when returned by the Government of the United States to the Admiralty at Halifax, will be placed at the disposal of the Canadian Government, for the purpose of continuing the exploration in which they are now engaged in Hudson Bay and Straits.

A COMMITTEE, consisting of members of the Italian Senate and Chamber of Deputies and other influential persons, has been formed at Turin for the purpose of furnishing Sig. Augusto Franzoj with the means of enabling him to carry out his project to explore the country between the Abyssinian province of Kaffa and the Lakes of Equatorial Africa.

THE most important paper read before the Paris Society of Commercial Geography at its meeting on the 17th ult. was one by M. Delaneil, the explorer of the northern part of the Malay peninsula. He described his discovery of a large lake [illegible] his survey of the isthmus of Krao, called Tale-Sab, which is bordered by fertile plains, where elephants and buffaloes [illegible] The people inhabiting this region have hitherto been called Samsams.

AT the last meeting of the Geographical Society of Marseilles M. Brémond read a detailed account, with numerous [illegible] travels in the kingdom of China.

THE first number for the current year (Heft 1 etc. Heft 2) of the *Geographische Blätter* of the Bremen Geographical Society contains papers on the forest districts of Bavaria, the [illegible] wanderings of the Esquimaux of Baffin Land, by D. [illegible] Schwatka's exploration on the Yukon, New Zealand past and present, the German journey of exploration through [illegible] America, and numerous smaller communications.

THE last number (Band xv. Heft 4) of the *Zeitschrift* of the Geographical Society of Berlin contains the following [illegible] A description by Dr. von Langsdorff of Old Cairo, situated about four kilometres to the south-west of the Arab quarter of modern Cairo; an account of the mission station of Otjimbingue in Damaraland, by C. G. Büttner; the first part of a [illegible]

hods and task of ethnology, by "Achelis"; a map of , with accompanying description, by Herr Richard and a note on the additions and changes made in the lministrative organisation of the Thüringian region. *ndlungen* (Band xii. No. 2) of the same Society con- icism by Herr Ernst, who has for some years had the historical and geographical departments of the rary at Berlin, of the methods in which the work of a bibliography of the geographical works relating to -a "Bibliotheca geographica Germaniæ"—is being

meeting of the Geographical Society of Paris on a letter was read from the French Consul at Asuncion y, giving details of the expedition sent by the Argen- rnment to explore the Pilcomayo, and to ascend to n frontier if possible. It has been found that, owing able rapids, the river cannot be utilised as a route araguay and Bolivia. The only practicable route is nd, the possibility of which was recognised in 1883 by r's expedition. M. de Cailland described the Pescadore to in the Formosan channel. The islands have excellent , and form the key to Formosa. M. Simonin read a e Indian population of the United States; and M. nier described his project of an aerial railway for

Y ARRANGEMENT OF THE APPARA- OF THE ROTATING MIRROR FOR SURING THE VELOCITY OF LIGHT[1]

NG now been engaged for a number of years in asuring the velocity of light by means of the rotating have succeeded in rearranging the apparatus in such a s, by means simply of two mirrors, one fixed, the vable, placed at a distance of a few metres from each obtain, even with a very moderate velocity of rotation, n of the image of a fixed object as large as may be theory and limited in practice only by the intensity of and the perfection of the optical apparatus.

cribe in a few words the plan of L. Foucault's cele- periment:—The rays issuing from a narrow aperture distance of 1 m., on a rotating mirror 14 mm. in dia- d, on being reflected there, traverse an object-glass near the mirror as possible. This object-glass throws of the aperture on a spherical concave mirror having a 4 m. placed at a distance of 4 m. from the rotating A second mirror, in all respects perfectly correspond- the first, receives the reflected pencil, which produces nage of the rotating mirror, and transmits a movable the aperture to a third mirror, and so on. Foucault's comprised five similar mirrors. The last, in which a ge was formed, reflected on the fourth the light, which is previous course and so came back to the rotating mirror, ain in turn transmitted it deviated in respect of its rota- n angle twice as large as that at which it had turned forming the double passage of the mirror, *i.e.* twice The velocity of rotation being 400 revolutions per Foucault obtained a deviation of 7 mm.

f the objections taken to Foucault's experiment and the deduced from it respecting the velocity of light, is the s of that deviation. It is known how he ingeniously he difficulty by substituting for the measurement of the that of the distance of the aperture from the rotating roducing a determined deviation. He did not, how- guise the fact that the advantage of this substitution is more specious than real, and he brought forward the n apparatus composed of a series of objectives and of a mirror, by means of which the passage of the light extended to several hundreds of metres. He had even at the Observatory, the place where his new experi- ght to be carried out.

to confess that, in endeavouring to take advantage of 's scheme, whether by means of object-glass or of mir- ruck on such difficulties as caused me to desist from the ion of my researches by either of the methods indicated. United States in 1879 Mr. Michelson put in operation eriment of the rotating mirror at great distances, but arrangement which brings the experiment much nearer

to the celebrated one of MM. Fizeau and Breguet than that of Foucault. The aperture from which the light issues was placed at a distance of about 30 English feet (9·15 m.) from the rotating mirror, the diameter of which amounted to 1¼ inches (3·2 cm.). A simple non-achromatic lens, 7 inches (17·8 cm.) in diameter, and having a focus of 150 feet (45·75 m.) was placed in such a manner as to throw an image of the aperture, seen by reflection in the rotating mirror, on the surface of a plain mirror, 7 inches in diameter, placed normally to the line passing through the centres of the two mirrors and the lens, at a distance of 1086·23 feet (695·80 m.) from the rotating mirror. The pencil then returns on itself, and gives an image of the aperture coinciding with it, point for point, when the mirror is fixed, deviated as soon as it rotates. The lineal displacement of the image during a rotation of 258 revolutions per second amounted to 114·15 mm. The advantage, however, of such a large displacement seems to be counterbalanced by the inferior quality of the image. A lens 7 inches in diameter, and with a focus of 150 feet will, even under the best conditions, necessarily give an image bounded by very large fringes of diffraction, which atmospheric agitations transform into a luminous blot so ill-defined that, as Mr. Michelson himself confesses, it is impossible to study the effect of the parallax due to the defect of coincidence of the plane of the image with that of the lines of the micrometer; in other words, there is no defined focus.

In all my experiments, therefore, it has been my aim to maintain the perfect accuracy of optical effects, such as had been achieved by Foucault, believing that it is of greater advantage to measure even the small deviations of a perfect image than the exaggerated displacement of a blot of light. I have consequently sought to amplify the deviations of Foucault without increasing the distance to be traversed by the light, and without having recourse to great velocities of rotation on the part of the mirror.

I call to mind, by the way, that Bessel noted, as a means of increasing the deviation, the return of the deviated ray on the rotating mirror. This method, which has never yet been applied, might be utilised by means of a series of little plain mirrors placed in couples on one side and the other of the rotating mirror, in such a way as to transmit the pencil alternatively on one and the other of the two parallel faces of the rotating mirror. With each reflection the deviation increases by a quantity equal to its primitive value.[1] But this process would greatly complicate the measurement of the path traversed by the light. The advantage contemplated by it may, besides, be secured by a method much more elegant and simple.

The apparatus I bring under the notice of the Academy consists purely of two mirrors, one fixed, having a diameter of 0·20 m., the other movable, 0·05 m. in diameter, the two placed at a distance of 5 m. from each other. Both are concave and spherical, and have the same radius of curvature, 5 m. The source of light is a narrow aperture cut in the silver, in the centre of the large mirror. The pencil emanating from it and entirely covering the rotating mirror is reflected by the latter, and returns to form on the surface of the fixed mirror a movable image of the aperture and of the same size. In each of its positions this movable image becomes a source of light; the rays return to the movable mirror, which concentrates them anew into a fixed image; this is the image of Foucault, which coincides with the aperture when the rotation is very slow, which is deviated in respect of the rotation when the latter is a little rapid. Suppose the velocity of the rotating mirror to be such that the lineal deviation is equal to the breadth itself of the aperture, the image will then come to be formed on the fixed mirror, rim to rim with the aperture itself. There it falls on the reflecting surface of the silver, becomes then a source of light exactly similar to the first, producing a second image deviated by the same quantity. The latter in its turn acts like the first, in such a manner that, if one could look on the surface of the fixed mirror, one would there be able to see, issuing from the aperture itself, an indefinite series of identical images placed rim to rim and indistinguishable from each other, except in respect of their regularly increasing brightness. If the velocity of rotation is increased, all these images will be found to separate from each other and form on the fixed mirror a series of equal luminous lines, separated by equal intervals from each other, and

[1] These plain mirrors, disposed in couples, might also be used to reflect and transmit in one constant direction the light scattered in all directions by the rotating mirror. By this means the advantage would be obtained of observing the doubled deviation of a much more brilliant image.

which will continue increasing their distance from each other, proportionately with the increase of the velocity. If one succeeds in determining micrometrically the distance of one of these lines from the original aperture, he will measure no longer the single deviation of Foucault, but as high a multiple of that deviation as may be desired. The distance of my two mirrors from each other being 5 m., and the velocity of the rotation of the mirror only 200 revolutions per second, the deviation will be five-eighths of that obtained by Foucault—*i.e.* five-eighths of 0·7 mm., or nearly 0·44 mm. The tenth image will consequently be at 4·4 mm. from the aperture.

To assure myself, above everything, of the existence of these multiple images, I employed Foucault's mode of observation, and placed before the luminous aperture, at a little distance from the fixed mirror, a plate of glass with parallel faces, inclined at an angle of 45° to the direction of the axis of the mirror. By this means there is thrown back laterally a portion sufficiently faint, it is true, but still a portion, of each of the deviated pencils which one receives in a microscope. There will then be seen, so soon as the velocity of rotation is great enough to give a continuous image, appearing on the rim of the image of the aperture a second, less distinct image, next a third at the rim of the second, increasing in breadth in proportion as the first is more and more deviated, and ending by separating from one another. With the electric light generated by a small gas-machine of half-horse power, or with the wan sun of these late days, I have managed to see as many as three images and catch a glimpse of the fourth. The actual result very well corresponded with my anticipations. What remains to be done is to improve the method of observation and increase the quantity of light.[1]

Suppose the tenth image is sufficiently intense to be observed, I cut away the silver of the mirror from a little rectangle with rims parallel to those of the aperture. The tenth image will come to be formed in this rectangle, all the following images will be suppressed, and the deviated pencil traversing the glass of the mirror, the posterior face of which is plain and polished, will be received behind on a prism of total reflection, which will transmit it into the micrometric microscope. The distance of the rim of the image from the rim of the rectangle will be measured; then, by an independent operation, the distance of this rim from that of the aperture; the sum of the two will give the line of magnitude of the deviation. It remains to ascertain the order m of this deviation. For this purpose the rotation of the mirror will be accelerated till the image of the order $m - 1$ comes to be substituted for that which was observed. Let n and n' represent the numbers of revolutions of the mirror per second, δ and δ' the linear values of the simple corresponding deviations, then

$$\delta = k n, \qquad \delta' = k n' \qquad \text{and so } \delta = (m - 1)\,\delta',$$

thence

$$n n = (m - 1)\,n',$$

whence

$$m = \frac{n'}{n' - n}.$$

The number of revolutions is measured electrically by the methods M. Cornu has so carefully discussed in his work on the velocity of light; I need not dwell on it. Finally, the measurement of the passage of the light is easily got at; it is that of the distance from each other of the centres of the surfaces of the two mirrors.

In order to observe a deviation of a rather high order, all that is needed is a sufficiency of light. Now, in this case, I manage to augment considerably the proportions of utilised light. In the first place the rotating mirror may be made to reflect on its two faces, care being only taken that both have exactly the same radius of curvature. In the second place, having suppressed every object-glass, I am able to utilise the pencil reflected by the rotating mirror throughout the whole space in which it gives a good image of the aperture, and this space is considerable, because the astigmatism resulting from the obliquity does not sensibly affect the rectilineal form of this image. It is, next, possible to tack on to the mirror of 0·20 m., of which I have spoken, a series of other identical mirrors placed at [illegible] distances in the plane of rotation of the pencil. The [illegible] identity of the radius of curvature is, besides, easily [illegible] for these mirrors than in the case of the two faces of the [illegible] mirror. It is, however, always indispensable that the [illegible] image given by this latter is reflected exactly on to the [illegible] each of the fixed mirrors.

I have also to remark that it is necessary that the [illegible] tance of the image observed from the aperture [illegible] to allow the observation to be made. For in the [illegible] the glass of the mirror and on its two surfaces there [illegible] ably arise a diffusion, as also reflections of the [illegible] to embarrass and even frustrate the exact vision of the [illegible] image when it is too near the aperture. I have [illegible] the actual apparatus ought, under good conditions, [illegible] image of the sixteenth order, perhaps even one [illegible] twentieth—that is to say, at 8·8 m. from the [illegible] be useful, however, to have recourse to an [illegible] considerable proportions.

If 20 m. is taken for the radius of curvature [illegible] and for the length of the simple passage of the [illegible] movable mirror ought to have a diameter of 0·20 m. [illegible] be impressed on it a velocity of rotation of [illegible] per second, the deviation calculated according to the [illegible] of Foucault will be:—

$$0{\cdot}7 \text{ mm.} \times \frac{40}{40} \times \frac{20}{1} \times \frac{50}{400} = 1{\cdot}75 \text{ mm.}$$

The displacement of the twentieth image will then be [illegible] which, measured to the hundredth of a millimetre, will [illegible] approximation of $\frac{1}{3500}$. Now I do not think [illegible] turn a mirror of 0·20 m. as many as fifty revolutions per [illegible] without causing deformation of its surfaces. The [illegible] the movable pieces of the dynamo-electric machine [illegible] sent day frequently attain a similar velocity.

It is my duty to make known to the Academy that [illegible] necessary for my first and long experiments were [illegible] supplied to me by M. de Romilly, to whom I [illegible] make this public testimony of my gratitude.

[1] The quantity of light utilised by this mode of observation on a glass is hardly the tenth of the actual quantity. The ratio of the geometrically decreasing progression representing the intensities of the successive images being 0·656, allowing 0·50 for the reflecting power of the silver, the brightness of the third image seen by reflection from a plate of glass is inferior to that of the eighth image seen directly. The reflecting power of new silver being 0·96, it would be possible by its means to attain to the sixteenth image.

ACCIDENTAL EXPLOSIONS PRODUCED BY NON-EXPLOSIVE LIQUIDS

III.

THE only real danger which may attend the use of [illegible] sponge lamps arises from accidental spilling [illegible] filling them in the neighbourhood of a flame, or [illegible] out the operation of filling in the vicinity of a light. [illegible] such casualties as have been attendant upon the use of [illegible] spirit as an illuminant have been mainly connected [illegible] keeping and handling of the supplies of this very [illegible] and are largely attributable to want of caution or to [illegible] ness. The salutary regulation prescribed by law, [illegible] containing the spirit shall bear a conspicuous label [illegible] dangerous character, has undoubtedly operated very [illegible] in diminishing the frequency of accidents with it, by [illegible] admonishing to caution. It is a matter for much [illegible] regret that the manufacturers of a class of minor [illegible] consisting of modifications of well-known types, [illegible] ordinary oil lamp replaced by the sponge lamp, [illegible] petroleum-spirit is burned, should have allowed [illegible] to induce them to mislead those who buy their [illegible] gard to the nature of the illuminant supplied and [illegible] devising a name for it which gives a false indication [illegible] being designed to create the belief that it is an article [illegible] manufacture, allied in character to a commercially [illegible] largely used in miners' lamps, while in reality it is a [illegible] article of commerce, the safe storage and use of which [illegible] special precautions and vigilance.

The lecturer took occasion to point out here, [illegible] that a large proportion of the accidents arising [illegible] ployment of petroleum or paraffin lamps were [illegible] to the occurrence of explosions. Thus the [illegible] of a lamp, whereby the liquid is brought into [illegible] warm portion of the lamp close to the burner, may give [illegible] liberation of vapour which, in escaping into the [illegible]

[2] Address delivered at the Royal Institution [illegible] March 13, 1885, by Sir Frederick Abel, C.B., D.C.L., [illegible]

Continued from p. 496.

lamp by blowing down the chimney. The landlord and an aged of the sufferers were witnesses of this assertion. The lamp fell from carrying between seven and eight pounds of oil, and was broken to pieces, when the woman took it in her hand, and having partially turned it down, proceeded to fill it from the chimney, an experiment attended, as might be expected, with the same result as the former one. The poor old woman was then left, as the landlord and his wife thought, in a fit state to be trusted with the lamp, and they retired to their own apartments. Shortly afterwards, however, the woman was found lying on the floor, with the lamp by her side, and the room filled with smoke. She was carried to the hospital, where she died on the following day.

air-space filled with that mixture, especially if the flame has been turned down, as the latter is thereby brought nearer to the reservoir. The sudden cooling of the glass, if it had become heated by the burning of the lamp, may also cause it to crack if it is not well annealed, and this cracking, or fracture, which may allow the oil to escape, may convey the idea that an explosion has taken place. If the evidently common practice is resorted to of blowing down the chimney with a view to extinguish the lamp, the effects above indicated as producible by a sudden cooling may be combined with the sudden forcing of the flame into the air-space, and an explosion is thus pretty certain to ensue, especially if that air-space is considerable. If the flashing-point of the oil used be below the minimum (73° Abel) fixed by law, and even if it be about that point or a little above it, vapour will be given off comparatively freely if the oil in the lamp be agitated, by carrying the latter or moving it carelessly; the escape of a mixture of vapour with a little air from the lamp, and its ignition, will take place more readily, but on the other hand it will probably be feebly explosive, because the air will have been expelled in great measure by the generation of petroleum vapour. If the flashing-point of the oil be high, the vapour will be less readily or copiously produced, under the conditions above indicated, but, as a natural consequence, the mixture of vapour and air existing in the lamp may be more violently explosive, because the proportion of the former to the latter is likely to be lower and nearer that demanded for the production of a powerfully explosive mixture. If the quantity of oil in the lamp reservoir be but small, and the air-space consequently large, the ignition of an explosive mixture produced within the lamp will obviously exert more violent effects than if there be only space for a small quantity of vapour and air, because of the lamp being comparatively full. If the wick be lowered very much, or if for some other reason the flame becomes very low, so that it is burning beneath the metal work which surrounds and projects over the wick-holder, the lamp will become much heated at those parts, and the tendency to the production of an explosive mixture within the space of the lamp will be increased, while, at the same time, heat will be transmitted to the glass, and it will be correspondingly more susceptible to the effects described as being exerted by its sudden exposure to a draught. Experiments have demonstrated that a lamp containing an oil of high flashing point is more liable to become heated than a comparatively light and volatile oil, in consequence of the much higher temperature developed by the combustion, and of the comparative slowness with which the heavy oil is conveyed by the wick to the flame. It therefore follows that safety in the use of mineral oil lamps is not to be secured simply by the employment of oils of very high flashing point (or low volatility), and that the use of very heavy oils may even give rise to dangers which are small, if not entirely absent, with oils of comparatively low flashing points. The occurrence of such an accident as that in the training-ship *Goliath*, already referred to, which was brought about by a boy letting fall a lamp which had been alight all night, and which was so hot that he could no longer hold it, appears to be primarily ascribable to the use of an oil of very high flashing point; and the accident at the Agricultural Hall furnished another illustration of the kind of danger attending the use of such an oil.

The character of the wick very materially affects not only the burning quality of the lamp, but also its safety. A loosely plaited wick of long staple cotton draws up the oil to the flame regularly and freely, and so long as the oil be not very heavy or of very high flashing point, and therefore difficultly volatilisable or convertible into vapour (by so-called destructive distillation), the flame will continue to burn brightly and uniformly, with but little charring effect upon the wick—that is to say, the extremity of the latter will only be darkened and eventually charred to a distance of much less than a quarter of an inch downwards, and it will not be until the partial exhaustion of the oil-supply diminishes the size of the flame and induces the user to raise the wick, that the latter will become more considerably charred. But, if the wick be very tightly plaited, and made, as is not unfrequently the case, of a short staple cotton of inferior capillary power, the oil will be less copiously drawn up to the flame; as a consequence, the length of exposed wick will be increased by the user of the lamp, and as the evaporation of the oil will take place more slowly from each portion of the wick which furnishes the flame, the heat to which the cotton is exposed will be greater, and the charring, which is fatal to the proper feeding of the flame by destroying the porosity of the end of the wick, will therefore more rapidly and to a much greater extent.

Even with wicks of the higher qualities, considerable differences exist in the rapidity with which the oil is raised to the flame. In Mr. Redwood's experiments, conducted with a number of English wick of good quality and with a very superior American wick, of corresponding dimensions, the quantity of oil siphoned over by the latter in a given time, was from 9 to 10 per cent. greater (according to the nature of oil experimented with) than that carried over by the English wick.

If the wick be at all damp when taken into use, its power of conveying the oil to the flame will be decidedly diminished, the capillaries of the fibre being more or less filled with water, and similarly, if the oil accidentally contain any water, this, in passing into the wick, will interfere with the proper feeding of the flame. As the oil is very thoroughly filtered as it passes during its transmission through the body of the wick to the flame, it is obvious that any impurities suspended in the oil will be deposited within the wick and will gradually diminish its porosity. For this reason the same wick should not be used for a great length of time, and it is decidedly objectionable to use a much greater length of wick than is necessary to reach the bottom of the reservoir, and to continue its use until it has become too greatly shortened by successive trimmings. On the other hand, the wick should always be of sufficient length to be immersed to a considerable distance in the oil. It is evident that the copious supply of oil to the flame will become impeded as the column of liquid which covers the wick in the reservoir becomes reduced in height; hence the supply of oil in the reservoir should never be allowed to get very low, not only because undesirable to have a large air-space which may be filled with vapour and air, but also because the burning of the lamp is injuriously affected thereby.

Some lamps of patterns first constructed in the United States are provided with what may be called a feeding wick, in addition to the wick or wicks which furnish the flame. The feeding wick is generally simply suspended from the lower surface of the reservoir and reaches nearly to the bottom of the reservoir, being so placed that it hangs against one flat side of the triple wick, and thus aids considerably the copious and uniform supply of oil by the latter. In certain lamps of recent construction the reservoir which contains the main supply of oil is so arranged (upon the principle of the old study or Queen's lamp) that it regularly maintains at a uniform level the supply of oil which surrounds the wick in a small central reservoir or cylinder separated from the main reservoir (excepting as regards the small channel of communication) by an air-space, which possesses the additional advantage of preventing the transmission of heat to the oil vessel. This kind of lamp is commonly made of metal; this is the case now with a very large proportion of the lamps in use, and unquestionably adds greatly to the safety of lamps, which, if constructed of glass or porcelain, are more liable to accidental fracture, quite apart from the question of possible explosion.

It has been proved experimentally that if the reservoir of a burning lamp be warmed, so as to favour the emission of vapour into the space above the oil, and a small opening in the side of the reservoir be then uncovered, air will be drawn into the lamp and form an explosive mixture with the vapour, which, ignited from the lamp chimney to the wick-holder, will be fired, and produce an explosion in the lamp. It is an interesting illustration of the very imperfect appreciation, by some lamp-users, of the conditions which, in the construction of a lamp, avoid or determine danger, that the reservoirs of some petroleum lamps are actually furnished with an opening in the upper surface, which is closed with a more or less fitting screw cap, and is intended to be used for filling the lamp with oil. Independently of the great element of danger which these presents, in consequence of the obvious temptation to the user to replenish the reservoir while the lamp is actually burning, it is very likely sooner or later to be the means of making the reservoir, in the manner above indicated, the source of necessary to determine the explosion of vapour therein.

Another source of danger introduced in the construction of lamps which should be sufficiently obvious, and to which reference was made when first discussing the causes of lamp explosions, consists in the provision in many lamps, of apertures of considerable size close to the burner, apparently with the object of affording a passage for the air or vapour in the reservoir which may expand as the lamp becomes somewhat warm.

work on the Odontornithes, or birds with teeth, and contains a full account of the peculiar order of mammals discovered by him during the last fifteen years in the early tertiary formations of the great central plateau in Wyoming. The old lacustrine basin of this region, where alone the remains of Dinocerata have hitherto been found, have already yielded parts of over 200 individuals, which are now grouped in three genera: Dinoceras, Marsh; Tinoceras, Marsh; and Uintatherium, Leidy. The last-named appears to be the most primitive type, and Tinoceras the most specialised, Dinoceras being intermediate. Of species the number cannot yet be determined, but thirty more or less distinct forms have already been recognised. In stature and movements it appears to have resembled the elephant as much as any other known type, differing from it especially in the shape of the skull, remarkably small brain, longer neck, and more bent fore limbs. It was by far the largest of all known Eocene animals. The paper is enriched with numerous illustrations, and with a map showing the region of Dinoceras beds.—On Taconic rocks and stratigraphy, with a geological map of the Taconic region, by James D. Dana. In this paper the author embodies the results of a fresh study, begun in 1882, of the Taconic region extending over parts of Massachusetts, Connecticut, Vermont, and New York. The rocks described comprise the Taconic skirts of the Taconic range, and subordinate ridges within the adjoining limestone area; the limestone formations on the east and west sides of the Taconic range; and the quartzite adjoining or within the limestone area. All these rocks are regarded as belonging to one system of Lower Silurian age, with the Taconic schists as the upper member of the series. The map is to a scale of half an inch to the mile.—Variations of latitude, by Asaph Hall. The author deals with Signor Fergola's recently-proposed plan for investigating variations of latitude by special series of observations made with the best prime vertical transit instruments on selected lists of stars. A chief feature of the plan is that the work is to be mainly differential, two observatories under the same or nearly the same latitude co-operating.—Notes on the Jurassic strata of North America, by Charles A. White. The paper is mainly a reply to the objections raised by Mr. J. F. Whiteaves, of the Canadian Geological Survey against the classification of certain exposed formations frequently occurring throughout Colorado, Wyoming, Dakota, Utah, and Montana, and usually referred to the Jurassic period.—Meteoric iron from Coahuila, Mexico, by M. T. Lupton. An analysis of a fragment of this meteoric mass, weighing about 192 lbs., yielded: iron, 91·86; nickel, 7·42; cobalt, ·50; phosphorus, ·27.—Optical projection of aconitic curves, by W. Le Conte Stevens. Optical presentations of a concord and a discord are shown projected on a screen by a simple and ingenious process.—Measurement of strong electrical currents, by John Trowbridge.—Divisibility of the Archæan formations in the North-West, by R. D. Irving. The region here investigated occupies, as indicated by the accompanying sketch-map, a tract some sixty miles in length between Lake Nemakagon, in North Wisconsin, and Lake Gogebic, in North Michigan. The Archæan rocks of this district are referred to the Huronian and Laurentian systems.—Mineralogical notes, by W. E. Hidden. Specimens are described of phenacite and Xenotime, from new localities; of Fayalite, from Colorado; of Zircon, from Canada; and of mitile and emeralds, from North Carolina.

SOCIETIES AND ACADEMIES

LONDON

Royal Society, March 19.—"On 'Transfer-resistance' in Electrolytic and Voltaic Cells." By G. Gore, LL.D., F.R.S.

The existence of this phenomenon has been [illegible] ever since the year 1831, and the question has been [illegible] many investigators. In the present paper [illegible] of methods by means of which its reality has been [illegible] Other methods are given for measuring the [illegible] "resistance," either collectively at the two electrodes [illegible] trolytic cell, or separately at each electrode. [illegible] the interference of polarisation, and of [illegible] measurements, are also described.

The influence of various circumstances upon the [illegible] were investigated—viz. strength and density of [illegible] resistance; density of current and size of electrode; [illegible] of the electrolyte; strength of ditto; combined [illegible] temperature; and chemical corrosion. The [illegible] phenomenon to size of plate in voltaic cells, to the [illegible] negative plates respectively, and to strength of [illegible] cells, were also examined, and the results are given.

The following are the chief facts established to the [illegible] That a species of electric "resistance," distinct [illegible] polarisation and of ordinary conduction-resistance, [illegible] in amount in different cases, exists at the surface [illegible] tact of metals and liquids in electrolytic and voltaic [illegible] this "resistance" varies largely in amount with [illegible] in the same solution, and with the same metal [illegible] solutions; in dilute solutions of mineral acids [illegible] strengths, or of different temperatures, and is nearly [illegible] easily corrodible metals which form quickly soluble [illegible] large with those which are not corroded; and [illegible] the case of those which by corrosion form insoluble [illegible]

The results of the experiments also show that the [illegible] current was "resisted" in different degrees by [illegible] metal when employed as an anode, and when used [illegible] also by the same metal when used as an anode [illegible] respectively; and that the proportions of such "[illegible] an anode and cathode of the same metal varied [illegible] different metal in every different voltaic [illegible] electrolyte), and at every different temperature; [illegible] resistance at the anode was usually smaller than [illegible] cathode; in some cases, however, where a film [illegible] the anode, an apparently reverse effect occurred; [illegible] from a given positive plate of a voltaic cell was [illegible] resisted by every different metal used as a negative [illegible] cell; and that by rise of temperature "transfer-resistance" [illegible] usually and considerably reduced.

They further show that this species of "[illegible] largely reduced by increasing the strength of current, [illegible] thus conspicuously distinguished from ordinary [illegible] resistance of the electrolyte. In consequence of the [illegible] "transfer-resistance" was greatly influenced by every [illegible] stance which altered the ordinary resistance, and [illegible] strength of current. The usual effect of diminishing [illegible] of current alone, by enlarging both the electrodes [illegible] the strength constant, was to diminish the "[illegible] ance;" and of enlarging one only, was to diminish [illegible] electrode and increase it at the other, the effect being [illegible] the altered electrode; but the influence of density [illegible] much smaller than that of strength of current. The [illegible] usually less "resisted," and larger with a small positive [illegible] and a large negative one, than with those when reversed. [illegible] tions of size or kind of metal at one plate of an [illegible] voltaic cell affected the "transfer-resistance" at the [illegible] altering the strength and density of the current.

"Transfer-resistance," therefore, appears to vary, [illegible] with every physical and chemical change in the [illegible] liquids, but also with every alteration in the current [illegible] "resistance" throws light upon the relative [illegible] positive and negative plates of voltaic cells, and [illegible] comparatively small influence of the negative one in [illegible] strength of current. Nearly all these conditions [illegible] results represented by average numbers obtained by [illegible] experiments.

Society, March 19.—Sir John Lubbock, Bart., n the chair.—Dr. J. Grieve and Mr. Chas. T. elected Fellows of the Society.—Dr. G. J. Romanes human crania from South Africa; one was that of bushman from Kruis River, Cango district, Gadte- ied through Dr. Stroud.—Mr. J. G. Baker drew specimen of a supposed hybrid between the two nd *Gasteria*, and grown in the Glasgow Botanic e also showed a curious new fern, *Polystichum polydactylon*, Hance, discovered by Mr. W. L.S., in the Island of Formosa.—A paper was hydroids from the collection of Miss Gatty, by Thirty-eight species distributed among twelve escribed as new. Among these the plumularian *adium*, is very remarkable, not only by the posses- ixed and movable nematophore, in accordance with genera, but by the fact that every hydrocladium n a cylindrical jointed peduncle. Among other re- significant forms is one to which the author gives the *ria heteromorpha*. In this are found combined on the yton no less than three morphological types, which, eparately, would be justly regarded as representing *Thuiaria*, *Dermasophia*, and *Sertularia*. Not- this singular combination of forms, the author does at the characters of the specimen justifies the con- new genus; and he regards the generic position of s determined by that one of the three forms which y prevailed in it. *Thuiaria heteromorpha* thus y marked way the indefiniteness of the boundaries ent zoological groups, and calls to mind a phe- to occur among plants, as in certain epiphytical hich the same stem has been observed to carry ble to several generic types.—Then followed a William Armit, F.L.S., viz. on plants met with oresby, Basilisk, O'Neill, and Margaret Islands, New Guinea, and in which a list of over 130 en.

Society, March 14.—Prof. Guthrie, President, in pt. Abney read a paper upon recent researches In general a hot body loses heat in three ways: by convection, and by radiation. In the case of ment of an incandescent lamp the loss of heat by nsignificant, and a series of experiments has been mine the amount of radiation—that is, the energy adiant heat for every unit of electrical energy e lamp. Mr. Crookes has investigated the sub- n in high vacua, the cooling bodies being thermo- d has come to the conclusion that, at pressures illionths and 1 millionth of an atmosphere, the s as the mean molecular free path. In the lements incandescent lamps of thin glass were ifferent degrees, the radiation being measured by It was found that, from 40 millionths to 10 mil- mosphere the radiation increases uniformly with essure, but that beyond this point it becomes A more important question is to determine the ion for any particular ray under the above con- was effected by placing a small thermopile in the of the spectrum. Plotting the results with watts d radiation as ordinates, the curves for each kind d to be very accurately hyperbolas with vertical ult gives a method for rendering identical the ight emitted by two lamps. We have only in n corresponding to a particular kind of light for then, by examining the curve corresponding to other lamps, find for what number of watts the same.—Prof. J. A. Fleming read a paper on rves of incandescent lamps. The author has er of statistics connecting the life, resistance, potential difference of incandescent lamps, and en with a view of showing the mutual relations s by empirical equations. A curve showing the ne of them to any other is called a characteristic up. Among the various results arrived at was of the law, announced by Prof. Ayrton and meeting of the Society, that for a certain class ential difference, minus a constant, varies as the by candles per horse-power. The constant, which, in the lamps examined, is about 28·7, is nearly the potential difference at which the lamp begins to emit light; hence the law may be put into this form: The effective potential difference varies as the cube-root of the efficiency. Using the results obtained, the author then solved the problem of determining the conditions for a minimum cost per candle, and obtained a result closely agreeing with that communicated at the last meeting by Profs. Ayrton and Perry. In answer to Lord Rayleigh, Dr. Fleming stated that he had not calculated the increase of cost due to a variation from the most favourable conditions; it had been shown, however, by Messrs. Ayrton and Perry that the increase of cost due to a variation of potential difference amounting to 5 or 4 per cent. upon either side of the value corresponding to least cost was very small.—Mr. C. Cleminshaw described some further experiments on spectrum analysis. These consisted of methods of obtaining the inversion of the sodium line in the spectrum of the limelight. The first consisted in concentrating the rays from the slit by a lens, just beyond the focus of which is a spoon in which sodium is ignited by a Bunsen flame. In the second method the burner and sodium are introduced between the lime and the slit, and carbonic acid is introduced into the flame. The result in either case is to cause the inversion of the D line. Prof. Guthrie, alluding to the pale blue flame produced by common salt in a coal fire, suggested that there might be more than a mere mechanical action produced by the carbonic acid. Mr. Cleminshaw, however, believed that the action was purely mechanical.—An abstract of a communication by Dr. John Hopkinson on Sir W. Thomson's quadrant electrometer was read by the Secretary. According to Maxwell, the deflection produced by a given difference of potential between the quadrants is given by the formula—

$$d = k\left(A - B\right)\left(C - \frac{A + B}{2}\right)$$

where A and B are the potentials of the quadrants, and C that of the needle. Dr. Hopkinson finds, however, that the constant k should be $\frac{k}{1 + hC^2}$, the quantity h being due to and depending on the unsymmetrical position of the needle with respect to the quadrants.

Zoological Society, March 17.—Prof. W. H. Flower, LL.D., V.P.R.S., President, in the chair.—Mr. Sclater exhibited and made remarks on a duck shot on Lord Bolton's estate in Yorkshire which appeared to be a singular variety of the Scaup (*Fuligula marila*).—Mr. W. B. Tegetmeier, F.Z.S., exhibited and made remarks on a pair of abnormal deer's antlers obtained in India.—Dr. F. H. H. Guillemard read a paper on the ornithology of the Sulu Archipelago, showing that the *avifauna* of that group is purely Philippine, and that the line of separation between the latter archipelago and Borneo lies between the islands of Sibutu and Tawi-tawi. Dr. Guillemard added fifty species to the list of birds hitherto known from Sulu, two of which were new to science.—A communication was read from Mr. T. Kirsch, of the Royal Zoological Museum, Dresden, containing descriptions of some new butterflies obtained by the collectors of Mr. Riedel in Timor-Laut.—A communication was read from Prof. W. Nation, C.M.Z.S., containing some notes on the Peruvian cliff-swallow (*Petrochelidon rufiventris*).—A communication was read from the Rev. H. S. Gorham containing a revision of the Phytophagous Coleoptera of the Japanese fauna, of the sub-families *Cassidinæ* and *Hispinæ*.—A communication was read from Lieut.-Col. C. Swinhoe, F.Z.S., being the second of his series of papers on the Lepidoptera of Bombay and the Deccan. The present paper treated of the first portion of the Heterocera.—Dr. Hans Gadow, C.M.Z.S., gave an account of the anatomical differences observed during an examination of examples of the three species of rhea (*Rh. americana*, *macrorhyncha*, and *darwini*).

Chemical Society, March 19.—Dr. W. H. Perkin, F.R.S., President, in the chair.—The following papers were read:—On the presence of choline in hops, by Dr. Griess, F.R.S., and Dr. G. H. Harrow.—Fluorene, Part III., by Dr. W. R. Hodgkinson.—Combustion in dried gases, by H. Brereton Baker, B.A.

Entomological Society, March 4.—The President in the chair.—Four new members were elected.—Mr. T. R. Billups exhibited specimens of *Coenlyptus insidus*, Stein, from Chobham.—Rev. W. W. Fowler exhibited the unique specimen of *Ceryton*

atratulum, Reit. ; and specimens of an Indian *Cassida* in which the colours were preserved. Dr. Sharp remarked on the colouring matter of the *Cassidæ*. Mr. Fowler likewise exhibited a microscopical movable stage, suited to entomological purposes.—Mr. W. F. Kirby exhibited a variety of *Spilosoma lubricipeda*, Esp., which had been found in the British Museum (Natural History), South Kensington.—Mr. A. G. Butler communicated a few observations touching M. De Niceville's recent suggestions on seasonal dimorphism in the Lepidoptera, which gave rise to some discussion.—Dr. D. Sharp remarked on the recent discovery of two different forms of spermatozoa in *Helops striatus*, Fonsc.—Papers read :—A monograph of British *Braconidæ*, Part I, by the Rev. T. A. Marshall.—Descriptions of new species of Languriidæ, by the Rev. W. W. Fowler.—On the discovery of a species of the Neuropterous family, *Nemopteridæ*, in South America, with general considerations regarding the family, by Mr. R. McLachlan.

Mineralogical Society, March 10.—The Rev. Prof. Bonney, D.Sc., F.R.S., President, in the chair.—Messrs. James Currie, Alfred Harker, and M. Alfred Lacroix were elected members.—The Secretary read a paper by M. H. Sjögren (communicated by Dr. Hugo Müller) on the crystalline character of graphite.—Mr. W. Semmons read a paper on a new discovery of connelite.—The balance sheet of the Society for the year 1884, which will be issued with the next part of the *Journal*, showed the Society's financial position to be satisfactory.

Institution of Civil Engineers, March 24.—Sir Frederick J. Bramwell, F.R.S., President, in the chair.—The paper read was on the electrical regulation of the speed of steam-engines and of other motors for driving dynamos, by Mr. P. W. Willans.

EDINBURGH

Royal Physical Society, March 18.—Mr. B. N. Peach, F.R.S.E., F.G.S., President, in the chair.—The following communications were read :—On certain peat and tarn deposits in the North of England, by Mr. Hugh Miller, F.G.S., Assoc.R.S.M.—Mr. Robert Kidston, F.G.S., described three new species of Fossil Lycopods from the carboniferous formation : *Sigillaria M'Murtrie*, from Redstock ; *Sigillaria Coriacea*, from the Newcastle coalfield ; and *Lepidodendron Peachii*, from Falkirk.—On the chemical composition of some samples of Scotch ensilage, by Mr. W. Ivison Macadam, F.C.S., F. Inst. Chem.—Specimens and sections of caseous tumours, found in the muscles of a hake, were described and exhibited by G. Sims Woodhead, M.D., F.R.C.P.E., who had received them from Dr. R. H. Traquair, F.R.S. These caseous masses were composed of broken-down muscular fibre, which appeared to have undergone a peculiar waxy or vitreous degeneration. Surrounding these was an area of young cellular tissue, with a considerable number of blood-vessels, and around this cellular area the muscles were undergoing the same peculiar waxy change. No parasite could be found, and it was suggested that the change might be due to violent muscular action. Dr. Woodhead also showed specimens of the liver of a fowl, in which were numerous caseous nodules. In these bacilli were found in very considerable numbers, giving the same reactions as Tubercle and Lepra bacilli. Mr. Owen Williams, M.R.C.V.S., in the discussion which ensued, mentioned that tuberculosis was often found in highly-bred fowls, and in rabbits.

PARIS

Academy of Sciences, March 23.—M. Bouley, President, in the chair.—Remarks on the map of France issued by the Dépôt de la Guerre to the scale of 1 : 200,000, with specimen sheets of a new map of France to the scale of 1 : 50,000 by Col. F. Perrier. Of the War Office map, the six first sheets, embracing the districts of Metz, Nancy, Vesoul, Troyes, Dijon, and Châlons-sur-Marne, are finished. The whole, comprising eighty sheets, 0·64m. by 0·40m., is to be completed within the year 1886, and will form a superb specimen of modern cartography.—Experimental researches on the electric excitability of the brain, properly so-called, by M. Vulpian. The author's experiments on the dog, cat, monkey, and other animals, lead him to infer that the arguments hitherto used to prove the excitability of the grey cortical substance at certain determined points are groundless, and fail altogether to support the hypothesis of local cerebral functions.—Remarks in reply to some criticisms of M. Friedel on the existence of the hydrate of chloral in the state of vapour, by M. L. Troost.—A comparative study of vessels from the [illegible] propelling forces, by M. A. Ledieu.—A simple demonstration of Lambert's theorem on the mutual action of the sun [illegible] and of a celestial body observed from the latter, by [illegible] Vieaire.—On the integers of total differentials, by [illegible] —Description of an electric pile acting with a single [illegible] fluid, and presenting special conditions of constancy, by [illegible] Mascart.—Chemical and physiological effect of hydrocyanic phyll, by M. C. Timiriazeff.—Relations between the absorption spectrum of the vapour of water and the telluric lines of the solar spectrum, by M. H. Deslandres.—On the preparation of ammoniac gas, by M. Isambert.—On a monochloruretted and monobromuretted isomerous camphor, by M. F. Gu[illegible] —On the di-ethylamido-a-butyric acid, by M. B. Tr[illegible] On the existence of three ganglia in the auditory nerve [illegible] forming a zone of cellules analogous to one of those [illegible] the retina, by M. E. Verrier.—On a new type of [illegible] largely represented in fossil vegetation, by MM. [illegible] and R. Zeiller.—A contribution to the study of the [illegible] in the West of France, by M. L. Crié.—On the [illegible] Côte-d'Or range, by M. J. Martin. Contrary to the [illegible] received opinion, which assigns this range to a period intermediate between the Jurassic and Cretaceous, the author shows that it is in reality posterior to the latter.—Supplementary remarks on the gigantic turtles of Madagascar, by M. [illegible] lant. From the remains found by M. Grandidier at [illegible] Amalitsate the author determines two distinct species, which he names *Testudo Grandidieri* and *Testudo abrupta*.—On the production of a new crystallised phosphate of manganese and the corresponding arsenate, by M. A. de Schulten.—Description of the cylindrograph, a new photographic apparatus, which by a simple rotation of the objective, enables the author to obtain views of the landscape embracing an angle of [illegible] by M. Moessard.

S. N. STOUT.

In Casks, 12/6 per 9 gals. In Bottle, 3/3 per doz. Impl. Pts.*

* Bottles charged 2/- per doz., and allowed at the same rate if returned; but they must be paid for with the Beer.

Neither sugar, saccharum, nor any of the many new Brewing Materials are used in the manufacture of the "S. N." Stout; it is Brewed entirely from the finest Malt and Hops; it is, too, more hopped than Stout is generally; therefore, besides being very nutritious, it is an excellent Tonic and particularly suited for invalids, ladies nursing, or anyone requiring a good strengthening beverage. It is a "Sound Nutritious Tonic," and very much recommended by Medical men.

LANE, LONDON.

MUTUAL LIFE ASSURANCE.

SCOTTISH PROVIDENT INSTITUTION,

EDINBURGH—6, ST. ANDREW SQUARE. LONDON OFFICE—17, KING WILLIAM STREET, E.C.

The ATTENTION of ASSURERS is directed to the SPECIAL ADVANTAGES obtainable in this Society, in respect of ECONOMY—EQUITY—SAFETY.

ECONOMY.—The Premiums are, in many cases, 20 to 25 per cent. under the usual rates, so that a Policy for £1000 may generally be had for the yearly payment which would elsewhere assure £1000 only.

EQUITY.—The whole Surplus is divisible among the Policy-holders themselves, on an equitable principle—no shareholder given to those by whose early death there is a *loss* to the other Members. From this source large additions have been made, and may be expected in the future.

SAFETY.—The Business (which for ten years has exceeded a Million yearly) is of the most select character, and conducted at the smallest cost.

The expenses, which are less than in any Office transacting so large a business, were last year under 9 per cent. of the Premiums, and little over 6 per cent. of the year's Income.

THE FUNDS accumulated from Premiums exceed **£5,000,000**, the increase last year being £333,383.

Only two Offices in the Kingdom (both older) have as large a Fund.

Claims under Policies now payable a Month after Proof.

Reports, with Tables of Premiums, &c., on Application.

J. MUIR LEITCH, London Secretary.

JAMES WATSON, Manager.

Just Published, with 28 Plates. Price £1 16s.

PHILOSOPHICAL TRANSACTIONS.

PART II., 1884.

CONTENTS.

13. On the Dynamics of a Rigid Body in Elliptic Space. By R. S. Heath, B.A.

14. Researches on Spectrum Photography in Relation to New Methods of Quantitative Chemical Analysis. Part II. By W. N. Hartley, F.R.S.E., &c.

15. On the Transfer of Energy in the Electromagnetic Field. By J. H. Poynting, M.A.

16. On the Motion of Fluid, Part of which is moving Rotationally and Part Irrotationally. By M. J. M. Hill, M.A.

17. On the Electro-Chemical Equivalent of Silver, and on the Absolute Electromotive Force of Clark Cells. By Lord Rayleigh, D.C.L., F.R.S., and Mrs. H. Sidgwick.

18. Influence of Change of Condition from the Liquid to the Solid State on Vapour-Pressure. By William Ramsay, Ph.D., and Sydney Young, D.Sc.

19. A Record of Experiments on the Effects of Lesion of Different Regions of the Cerebral Hemispheres. By David Ferrier, M.D., LL.D., F.R.S., and Gerald F. Yeo, M.D., F.R.C.S.

20. On the Comparative Morphology of the Leaf in the Vascular Cryptogams and Gymnosperms. By F. O. Bower, M.A., F.L.S.

21. Conditions of Chemical Change in Gases: Hydrogen, Carbonic Oxide, and Oxygen. By Harold B. Dixon, M.A.

Published and Sold by HARRISON & SONS, St. Martin's Lane.

Separate Copies on Sale by TRÜBNER & CO., Ludgate Hill.

NEW VOLUMES IN THE

INTERNATIONAL SCIENTIFIC SERIES.

TREDGOLD'S "CARPENTRY"

mentary Principles of Carpentry. By Thomas Tred-old, C.E. Sixth Edition, by E. Wyndham Tarn, M.A., rchitect. (London: Crosby Lockwood and Co., 1885.)

MR. TARN has for a good many years enjoyed a high reputation amongst the profession of archi- s as a writer upon the practical principles of building rded mathematically. Tredgold's treatise on Car- try has for a very long time indeed possessed the est reputation as a much more than elementary book eference upon that important department of building truction which deals with timber work; it has been blished time after time in the form of the old- ioned substantial quarto which used to be in vogue re we were encouraged to expect to read as we run. quite in accordance with the fitness of things that dgold and Mr. Tarn should come together, and the fish building world will scarcely require to be told the result is satisfactory. The new edition before us fact a readaptation once more of the excellent erial of the old standard treatise to the changing con- n of our mechanical knowledge and skill. The or's mode of treating his subject has been retained t; and we still have the well-known sections upon sures, resistances, floors, roofs, domes, partitions, ers, bridges, joints, and timber. Whether this par- ar arrangement is the best, is a question scarcely h asking, at least on behalf of the less fastidious ism of those practical designers of carpentry who here constitute the overwhelming majority of ers; but the editor has certainly not found it to be bar to the importation of new matter in his own way. he section he has introduced Prof. Clerk Maxwell's universally appreciated system of diagrams of press- whereby the mere application of a common drawing to the component lines of easily constructed geo- ical figures saves all further trouble and uncertainty scertaining the precise strains which the several bers of a truss have to bear. In other sections the pted formulæ of calculation, given only empirically Tredgold, are mathematically demonstrated. The iar tables of strength which supply the values of aots are "corrected" to accord with recent experi- s more delicately and adroitly conducted, and several tables of the kind are added. The consequent ion of Tredgold's "rules" and tables of scantlings been thoroughly and carefully done; and various s of more advanced construction are duly developed. difficult subject, the theoretical thrust of domes—for actice there ought to be none—is taken in hand matically, and a short chapter is added on stone ng. The important items of scaffolding, shoring, dams, and so on, have been also introduced. The kable timber bridges of America—rough and ready e of the best—have been taken account of as they ; and certain amendments which are made in t of the plates serve in a reasonable measure to ute new trussing for old. Lastly, the description nature and properties of timber is largely modified to meet the advanced knowledge of the day. With all this, the Tredgoldian character of the treatise is dutifully preserved; and so we may say it ought to be, for to modernise Tredgold too much would certainly not improve him. One of the prominent merits of the work consists in the unusually large number of illustrative plates, all to a useful scale. If these do not represent many of the more modern designs in timber work, they frequently offer examples to the student which are all the better in one respect—they exemplify that substantiality of construction which is is too much the tendency of scientific precision almost to discourage. It is a good maxim in carpentry as in most other departments of building, to make the structure not only strong but stronger than strong; and Tredgold always leans in that direction. The word *economy* is much employed amongst us; but, whereas its original and proper signification pointed only to skilful administration, its meaning with us is very much like mere parsimony. Waste of material is the bugbear of our builders, and almost still more of our architects. It need not be denied that mathematical science is in a certain way provocative of such parsimony; indeed, lightness of construction is regarded as an academical virtue in both architecture and engineering. But a moment's reflection ought to satisfy alike the most scientific and the least that true science is as much averse to parsimony of substance as common sense is. The strength of building materials can only be determined by extremely delicate experiments upon "breaking" strains, from the results of which the "safe" strains have to be deduced by estimate; and this, no doubt, becomes matter of opinion. The question is, what proportion of the breaking strain shall be recognised—almost arbitrarily—as the safe strain? With the single exception of iron, timber is the material with reference to which this matter of opinion is the most definitively settled. The reason is this:—The breaking strain must be instantaneously applied; this is essential to precision of tabulation. The safe strain is that proportion of this instantaneous breaking strain which the material will bear permanently without any risk of its elasticity being eventually overcome and a commencement made of that disturbance of the structure of the material which, once begun, increases in a geometrical ratio until the end is ruin. It is accepted, therefore, that the proportion of an ascertained instantaneous breaking strain which has to be recognised as the limit of a permanent safe strain is one-third, one-fourth, and so on, according to the character of the material. What does this mean? It means that a greater strain than this proportion would in time, with one accidental circumstance and another, produce a commencement of instability. Perhaps it is to be regretted that this question is still disposed of so empirically as it is; we might at least in these days have express observations made and reduced to what system might appear. Tredgold's rules turn very much upon the manifestations of flexure; and this, of course, is not only another way of dealing with the matter, but one which affords at any rate a basis upon which mathematical formulæ may be arrived at. On the whole, Tredgold is an old-fashioned writer, empirical and practical; but he is none the worse for that, perhaps all the better. Mr. Tarn has accepted the duties and reasonal-

qualities of a scientific ally, and we have pleasure in testifying that he does his work well, and that he does not overdo it.

THE MYRIOPODS OF AUSTRIA

Die Myriopoden der Oesterreichisch-Ungarischen Monarchie. 2te Hälfte, "Die Symphylen, Pauropoden, und Diplopoden." Von Dr. R. Latzel. (Vienna: Hölder, 1884.)

WHEN we say that the second volume of Dr. Latzel's work is in every way equal to the first we are according to it high praise. The first volume, that which dealt with the Chilopoda, has fully proved itself to be indispensable to every student of the Myriopoda, and it seems to us certain that this second volume, dealing with the other orders, must soon be accorded an even more important place in the literature of this subject. Nine years of close attention to the study of the myriopods have enabled Dr. Latzel not merely to complete a monograph of the species inhabiting his native country, but to complete it in such a manner that he has written a book which must be useful to the student of the myriopoda of any country. Not only has Dr. Latzel given minute descriptions of some 170 species, but he has also furnished tables which make it a matter of ease to determine the genus of any myriopod.

There has been unfortunately among those who have specially devoted attention to myriopods a tendency to create numerous new species on very insufficient grounds. By relying solely on characters of importance, Dr. Latzel has to great measure escaped this tendency. It is true that in the volume now under notice he has described a new genus and thirty-five new species. Possibly further observation may reduce this number; but when we remember the extent of area embraced by the Austro-Hungarian Empire, and the little attention which, comparatively speaking, has been paid by naturalists to myriopods anywhere, we must admit that thirty-five is no excessive number of new species; indeed, those who are familiar with the writings of others who have described myriopods must feel thankful that it is so small. A careful synonymy has been given of each species described; this is one of the most useful features of the book, as in this part of his work Dr. Latzel seems to us to have been singularly successful. It can have been no easy task to reduce to order the bulky mass of existing nomenclature; but Dr. Latzel has spared no pains in examining and comparing the types, generally insufficiently described, of his predecessors. It is much to be wished that some capable observer would take in hand to examine the types of the earlier English describers of myriopods, especially with regard to the Chilopoda described by Newport, and compare them with the types of Continental writers, for, so we fancy, the synonymy would be yet further reduced to order. Here we may refer to the only point in nomenclature which we regret in Dr. Latzel's book. He has adopted the specific name *vernalis*, Meinert 1868, for an animal which Dr. Latzel evidently suspects to be, and which we have no doubt is, the same as that described by Leach in 1814 as *Julus pulchellus*.

One admirable feature of this work is that, where possible, full descriptions are given of the young stages of each species. As to the details of the work there is no much room for criticism. Dr. Latzel has recorded in his work the results of all recent researches into the minute anatomy of the myriopods. Embryology, however, has not received a very large share of attention, but references are given to all writings on the subject. Dr. Latzel differs from some American authorities in looking on Scolopendrella as a true myriopod, and places the Symphyla as intermediate between the Chilopoda and the Pauropoda. We may here note that Dr. Latzel agrees with Menge in considering those organs which Ryder has described as tracheæ in Scolopendrella, as being merely chitinous supports for muscle-attachment. These are the same organs which Wood-Mason (*Ann. Nat. Hist.* 1885, 53) considers are of the nature of segmental organs.

A short notice of fossil myriopods is given, based chiefly on Scudder's researches into the fossil species of insects. Scudder's conclusion seems to us to be in many points erroneous, and at any rate to be premature and based on insufficient knowledge, but as no fossil myriopods have yet been found in Austro-Hungary we can only be thankful to Dr. Latzel for dealing with fossil forms at all. The same must be said with regard to the notice of the extinct Malacopoda. No species of Peripatus has yet been discovered in Europe, but, though we may not agree with him, it is interesting to know that one so qualified to judge as Dr. Latzel, looks on Peripatus as forming an order equivalent to the other orders, the Chilopoda, the Symphyla, and the Diplopoda. A most useful bibliography, brought down to the date of publication, is comprised in the work. The execution of the sixteen plates, showing morphological details, is excellent in every way.

OUR BOOK SHELF

Examples in Heat and Electricity. By H. H. Turner. (London: Macmillan and Co.)

THIS is a Cambridge collection of problems and riders extracted mainly from the Smith's Prize, Trepos, and College papers of the last dozen years. The compiler (for there is nothing to be called authorship) has done, on the whole, judiciously done; and the printing is usually clear and accurate, considering the complexity of many of the formulæ. The book is designed specially as a help to candidates for mathematical honours, and will undoubtedly prove useful to them; possibly, perhaps, to a few private students.

But to the natural philosopher the book presents some points of curious interest. For, in these seventy pages alone, may be found (by all who know the subject) important part of the Cambridge system, alive or in process condition and during its recent development. Here, for there we detect at a glance the lion-claw of the true physicist, and can, unhesitatingly, write against a question the name of Stokes, Thomson, Clerk-Maxwell, &c., so strongly marked is the individuality of these men:—who claim to physics, thus propounding nothing unphysical; and who use mathematics as a necessary instrument of expression, neither courting nor shunning mere technical difficulties. Each of their questions stands out like a green oasis in a sandy desert! The rest of the contents (except what is but thinly-veiled "book-work") is mainly the work of *Examining Mathematicians*—the men who use physical facts (or fancies) as mere pegs on which to hang complex catenaries of formulæ; to whom *pi* or *e* or *i* come quite as naturally and as usefully as the laws of Boyle and Charles; the men who can explain the motion of

ressure of a gas or the electric resistance of a wire es out" negative! To such men the recent introon of the subjects of heat and electricity by the l of Mathematical Studies, and the appearance of son's *Electrical Papers*, Maxwell's splendid treand other kindred books, have been happiness l. Open any one of these books, at any place, oncoct from it by whatever assumptions (however sical) are necessary, a problem which shall lead to ptic integral or a Bessel's function, and there you This cannot long go on without seriously impairing ogress of physical science in our great mathematical sity. Mathematics is, in itself, a right noble and y study; but the embryo physicist should, from the e taught to regard it as (for him) an indispensable ry only, not a source of natural (?) laws. The whole lure is thoroughly characteristic of the Cambridge lay. It has, among its professors and elsewhere, of the foremost of living physicists and mathe-ians, as well as others destined in time to take r rank:—but does not utilise them. Even its *one* est of mathematical merit, real because conducted ch men, the Smith's Prize Examination, has just bolished! So, it has a magnificent boat at the of the river," but *not one member* of that crew is o encounter Oxford at Putney! What can be ed, either in the boat-race or in the more arduous over the scientific course, but thorough and most ed defeat?

ntial Calculus for Beginners, with a Selection of y Examples. By Alex. Knox, B.A. (London: millan and Co., 1884.)

ittle book deserves hearty welcome from those who gaged in leading forward students to the higher natics; not so much as a substitute for any other at present in use, but as presenting a carefully-d set of illustrations of infinitesimals, limits, and inite coefficients, which a student may profitably through before entering upon the usual formal s on the calculus.

know of no work in English comparable with the since De Morgan's "Elementary Illustrations of ferential and Integral Calculus."

special symbols of the subject are not introduced e work before us, attention being directed to the inciples involved in the method of the calculus; the chief aim of the author throughout is to give ner a firm grasp of the idea of a differential co-—a fundamental notion which, in the minds of ers, is usually shrouded in a haze. Care is taken one at a time with the difficulties which present lves in this subject. The book is divided into sections, the latter two or three dealing with suc-differentiation, Maclaurin's theorem, and maxima nima.

before new principles or processes are introduced, eavour is made to insure a precise comprehension eaning of terms already employed by the student. e freshness of treatment, as well as the clearness ich the author brings before the mind the exact g of such terms as "point," "line," "superficies," irst section of this book, will awaken the interest at the attention of even an indifferent learner.

of the sections are independent of each other. much variety of illustration, the central principle ooked at from different points of view. A distin-feature is the great use made of arithmetical ions, many examples of the method of finite ces occurring.

es the usual geometrical treatment based on New-emmas," the ideas of time and motion are freely ed, and illustrations taken from elementary ics.

The book closes with a set of examples worked out in full, and a series of one hundred easy exercises, the answers to which are appended. A. R. W.

LETTERS TO THE EDITOR

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts. No notice is taken of anonymous communications.

[The Editor urgently requests correspondents to keep their letters as short as possible. The pressure on his space is so great that it is impossible otherwise to insure the appearance even of communications containing interesting and novel facts.]

Rock-Pictures in New Guinea

A FEW years ago I mentioned in a paper in *Globus* (lxii. 94) that Mr. Th. B. Leon had reported the existence of pictures on rocks he had seen in the Ogar and Arguni groups of islands (south part of McCluer inlet), and that the officer in command of H.N.M.S. *Batavia*, who had been charged to make further inquiries, had not been able to find them. At that time Mr. Leon's account had not been published in the regular issue of the *Bataw. Genootschap*. Since then, however, explorations by Mr. van Braam Morris, whilst on his voyage in New Guinea in 1883, and by some of the officers of H.N.M.S. *Samarang*, have resulted in the discovery of rock-pictures similar to those spoken of by Mr. Leon. The papers giving an account of these explorations (including Mr. Leon's) have been published in a recent number of the *Tijdschrift voor Indische Taal-, Land-, en Volkenkunde* (xxix. pp. 582-591), and an abstract of their contents may be interesting.

One day Mr. Leon set out from the kampong (village) on Arguni, situated on the island of that name, for the purpose of fishing. In the beginning, on account of the surf, he kept at a great distance, but the third island of the group he was able to approach. He perceived the distinct representation of a human hand, painted in white, and surrounded with red spots, and other drawings in white, which appeared to be meant for letters, though traced in characters unknown to him. Afterwards, on penetrating between two other islands of the group, he saw several hands, all similar to the first, and accompanied by similar drawings. He was not able to land; he estimated the height of the place at which they were drawn on the rock to be from 75 to 150 feet above sea-level, the hands being about three-quarters of the way up, and the other figures about 10 feet higher still. The hands were of all sizes, representing those of children, of full-grown men, of giants, and were in great numbers. He fancied the characters bore some resemblance to the written signs in use amongst the *Orang Kling*, the *Orang Bugis*, and the *Orang Mangkassar*; they were certainly not *Javan* or *Malayan*. He was greatly puzzled as to how they could have come there, since the face of the rock was perfectly perpendicular, and without any projections or caverns, as far as he could perceive. The only explanation he can suggest is that they must have been done at a time when that part of the rock-surface was nearer to the level of the sea, or the outward form of the rock must have been changed on that side by losing ledges or projections by which the native draughtsmen may have approached the place. It will be readily understood that the natives attribute these drawings to *Kawadi*, the prince of evil spirits, who, in their opinion, has his dwelling in one of the small islands, and of whom they are naturally greatly afraid. On another island Mr. Leon discovered a huge stone, which would probably require half a dozen men to lift it, rudely shaped like a hallock, and surrounded with several other stones, evidently arranged on some fixed plan.

Mr. van Braam Morris says:—On September 16, 1883, I came to McCluer inlet, and was told by the native chief that the figures I was in search of were to be found on Arguni, or the islands to the west of it. I discovered them on a small island a few hundred yards from the mainland. The shores of both the island and the mainland rose perpendicularly from the water, and in the rocky face of the former, about 5 feet above high-water mark, the surf had eaten out an excavation from 3 to 5 feet wide, thus leaving a narrow platform, on which several small *prahus* were deposited, some of them being 3 feet long. Various figures were drawn on the rock above, especially hands, both of full-grown people and of children. A hand had evidently been sketched in outline from

a living model placed against the wall, and coloured to a depth of 6 inches all around it. The native chiefs who accompanied the Resident said that the remains of the Hill-Papuans had formerly been deposited here, but were now interred with Mahommedan rites; there were indications, however, that some *prahus* had been recently lodged on the platform.

Though the most astonishing part of Mr. Leon's report, viz. the difficulty of drawing the figures on the rock at a considerable height above the sea, is not encountered by Mr. van Braam Morris's experience, it is not proved that the latter explored exactly the same place as Mr. Leon. But just this point (the considerable rising of the islands) is most plainly stated with regard to the Ke Islands by Messrs. Alliol, Mol, van Slooten, Meijboom, and Deijl, of H.N.M.S. *Samarang*, which at the time of their visit lay off Tual (5° 37' 30" S. lat. 132° 44' E. lat.), island of Little Ke. These gentlemen were invited by Mr. Langen, the head of the English settlement there, to visit with him the north-western part of the island; after having steamed for three-quarters of an hour they dropped anchor *vis-à-vis* Kalumit, a village at the base of a hill, about 200 metres high. They went to the top to see there some idols situated in a small settlement. I pass over this part of the narrative, and take it up after they had descended from the edge of the rock, where they had found a burial-place belonging to the kampong, which is on the top. A tolerably well-made flight of ironwood steps allowed the visitors to descend easily; after about half an hour's walk they came to the "necropolis."

On the rock near it they discovered representations in red of various figures—human hands, with the fingers spread out; imitations of human heads; a fight between men armed with *klewangs* (= cutlass), and other figures which they took to be representations of the evil spirits, outlines of ships, &c. Though the heads were rudely drawn, the hands, which were fewer in number, were remarkably well done. The place where the drawings are seem to be quite inaccessible to human beings. In the rock are also caverns which are rather difficult to approach. In one of them two gongs and some pieces of bamboo were found; at the entry fragments of broken glass had been spread, probably to prevent visitors from entering. It must be mentioned that the rock, from the base to the top, was covered with sea-shells. Attention is repeatedly drawn in the report to the circumstance that it seems incomprehensible how the pictures could have been drawn on the rock, which overhangs.

The natives connect the rock-pictures with the burial-place on the top of the cliff. Near the edge of the steep descent stand two houses, which serve as mortuaries, one being close to the dwellings of the natives, which are surrounded with a stone wall. These two houses are built of ironwood; on the roofs there are two pieces of wood, the one in the shape of a prow, the other in the shape of a keel. On the latter are two figures, a dog and a bird; a stick bearing a piece of white cloth is stuck into the bird's body. The walls are 4 and 3 metres, and in the shorter, which faces the sea, there are two doors, through which the coffin is carried; inside this hut they saw two coffins with fruits and a bottle of oil which had been left for the spirits.

The natives, who called themselves Hindoos or heathens, a name which of course has no ethnographical significance, but is merely used to distinguish them from their Mahommedan neighbours, said that when a dead body was placed in the hut the spirit was conducted by the bird or the dog on the roof to the caverns where it is to abide. In token of its arrival the animal draws a figure on the rock. The natives who accompanied the explorers durst not set foot within the caves.

It was also said that the bird and the dog were merely symbols. The soul of the deceased, on leaving the body, flies as a bird through the air or runs as a dog over the earth, till it reaches the abodes of the spirits—the caverns—unseen by living men. Every soul that reaches this haven draws a figure on the face of the cliff. In explanation of the contest between human beings and evil spirits in the pictures, they said that the latter try to prevent the souls from reaching the eternal dwellings; but they cannot hinder those who have led good and honest lives, though those who have done wickedly are carried off by the evil spirits.

The officers, judging from the many articles in gold and silver which were found in the caverns, concluded that they must formerly have been used by pirates as places of refuge and for hiding their stores, and that they were then nearer to the level of the water. On this view the drawings on the rocks would answer a double purpose: they would keep the superstitious from approaching the caves, and would also act as a landmark for the pirates themselves when returning from [illegible] to them the places where their treasure was hidden.

Without hazarding any opinion upon such interpretations, I wish to state, merely by way of summary—

(1) That Mr. Leon's evidence, combined with the [illegible] officers of the *Samarang*, would seem to indicate that the surfaces of certain islands in McCluer Inlet and of the Ke group have been considerably elevated.

(2) That the rise has probably taken place at no distant [illegible] but how long since cannot be determined until (perhaps) the close scientific examination.

(3) That Mr. Morris's explorations, taken in conjunction with the foregoing, suggest that the elevation is not a general one, but, though observed at distant points, is limited to certain islands of different groups, or even to particular sides of them.

Stuttgart, March 18 EMIL METZ

Mr. Lowne on the Morphology of Insects' Eyes

PROF. LANKESTER appears to me to be fighting his battle under cover. First he sends his lieutenant into the field, and then he appears himself, in the guise of an independent [illegible] But inasmuch as he has virtually accused the referee of the Linnean Society of having published a paper unworthy of a place in the *Transactions* of the Society, I feel fully justified in bringing him out into the open.

The anxiety expressed by Prof. Lankester on behalf of the Fellows of the Linnean Society, as to whether my paper was refused by the Royal Society, is manifestly insincere; he knows as well as I do, that the paper was never refused by the Royal Society. As Prof. Lankester is taking undue advantage of the secrecy which attaches to the referee, I shall state the facts with which I am personally acquainted, and I doubt not these will place the whole case in a very different light from that which Prof. Lankester has endeavoured to shed upon it.

It is evident Prof. Lankester wishes to make it appear that the rejection of my paper by the Royal Society confirms his strictures and those of his lieutenant, and enables him safely to attack the Linnean Society under cover of the Royal. Now I believe that every one who was concerned in the publication of my paper knew perfectly well that Prof. Lankester was not the referee to whom it was submitted by the Royal Society. Prof. Lankester wrote to me himself, and stated that the paper had been so referred. Although I then felt sure of its rejection, I should not have had any reason to complain, if the rules of the Royal Society had been carried out, and the paper had been submitted to a second, entirely independent referee. Prof. Huxley, in his opening address to the Royal Society on his election as President, stated that every paper was considered by two entirely independent referees. Now, in my case the second referee was Prof. Schäfer. I do not think it right to refer my paper to two colleagues intimately associated in the same school, and I am sure that no consultation should take place between the referees pending their decision. Yet Prof. Schäfer had Prof. Lankester's adverse opinions expressed in my presence before he came to any decision himself—at any rate before making any report; and he confessed to me that he had no special knowledge of the literature of the subject on which he was called upon to give an opinion.

Under the circumstances I feel justified in stating that, if the Royal Society had rejected my paper, it would have been by the rejection by Prof. Lankester; and I feel sure that an independent referee would have done exactly what was subsequently done on behalf of the Linnean Society.

Prof. Schäfer recommended me to withdraw my paper. I petitioned the Council of the Royal Society to allow me to do so, and the paper was returned to me. If this be a rejection my paper was rejected.

I then presented it to the Linnean Society, and to all I told the Zoological Secretary everything that had happened. The result was that, after some delay, the paper was ordered to be printed in the *Linnean Transactions*.

I could hardly have conceived it possible that any scientific man could have descended to such a device in combination with his own views as to pretend that the Royal Society had formed an independent judgment under such circumstances. Prof. Lankester has succeeded admirably in rendering himself personal as a representative of the Royal Society—a fact which

ould have no doubt incited his just indignation if it had been erformed by his friend "Sludge," of spiritualistic celebrity.

I cannot help remarking on the coolness of Prof. Lankester's sertion, that my views are "undeniably based upon a mistaken terpretation of defective preparations." Prof. Lankester idently thinks his opinion final—but he is bold to say it is undeniable."

My sections have been seen and approved of by a great mber of competent histologists and zoologists, and, although ne of them are not so pretty as those prepared by the paraffin thod which Prof. Lankester extols, they certainly show a great al more. The paraffin method is well known to me, and I have umined a great number of slides prepared by it. I have possed a series of sections so made in the Cambridge laboratory an excellent histologist, and have rejected them as worthless: y show nothing but the connective tissue framework. Nerve es and nerve end organs are alike destroyed.

The whole question of the effect of reagents on the tissues is ide one. The paraffin process destroys much which remains the cocoa butter process, first devised by Prof. Schäfer. I em this process far superior to that now used in the laboratory Cambridge, and by Prof. Lankester and his assistants. I uld not fear to place my specimens side by side with Prof. kester's before an unbiassed histologist; and I am content wait the decision of future observers upon my work. New s are met with little favour by those who are committed to ones, and, whether I am right or wrong, I expect no justice a critic who shows such determined bias as Prof. Lankester.

BENJAMIN T. LOWNE

Prof. Lankester imagines that he has any complaint to against the Council of the Linnean Society for having shed Mr. Lowne's paper, I must decline to consider the ct with him in your columns. He is himself a Fellow of ociety, and the anniversary meeting of the Society is due month. If he then thinks it wise to ask any questions upon ubject, I shall be in my place and most happy to answer

GEORGE J. ROMANES,
Zool. Sec. L. S.

Thought presents itself among the Phenomena of Nature

your issue of the 12th inst. the Duke of Argyll asks, "Is any difference in this respect between molar and molecular n?" namely, as regards the persuasion which most men ain that where there is motion there must be some "thing" re. The answer to this question appears to be the very one that there is the following fundamental difference between motions and *some* molecular motions, and that it intimately ns that belief. *All molar motions are secondary motions*, y consist in the drifting from place to place of underlying s (and, indeed, in the case of those motions which human can perceive even with the utmost aid of the microscope, nsist in the drifting from place to place of vast accumu- of such underlying motions), while, in contrast to this, re *some molecular motions which are primary—i.e.* which other motions underlying them, and which do not consist drifting from place to place of more subtile motions.

Grace correctly expresses the common opinion in the ig words—that "an atom[1] is only conceivable as an ulti- rticle of matter." Now the term "particle of matter" tatement needs to be scrutinised. As commonly under- means something minute which we should be able to feel r perceive by some of our senses were it not for the blunt- those senses; and this, as science shows, means that *certain specific motions* are present, viz. motions of those particular kinds which are competent, indirectly and through a long chain of intermediate steps, to finally occasion visual, tactual, or some other sensation in our minds. The statement, accordingly, as commonly understood, *really* amounts to this—that no motion can be present unless certain underlying motions are also present!

But to the uninstructed apprehension the statement has quite a different meaning, a much fuller one, and one which lies outside the domain of motion. Before they have made very careful investigation, men do not know that there is no green colour in grass or hardness in a rock. They are unaware that what is really going on in the grass is not a state of greenness, but vast myriads of motions,[1] each of which is repeated about as often every second as there are seconds in thirty millions of years, which motions in the grass occasion undulatory motions around of a like rapidity, some of which occur within our eyes, and, acting upon some compound or compounds in the black pigment which lies behind the retina, produce there an effect (probably a fugitive photographic effect consisting in some chemical change of one or more of three compounds in the pigment). This change, whatever it is, excites the optic nerve to make a stir within the brain, and *it is this last motion* (which we may safely say is utterly unlike the external phenomenon, though uniformly resulting from it through the steps enumerated above), which is what determines the perception of green in our minds. Similarly, when the vast accumulation of molecular motions which is called my finger approaches that other accumulation of motions which is called a rock, these motions act on each other, and my finger is compressed upon certain nerves, exciting them to produce those motions within my brain which, though quite unlike the motions outside, are the motions that are really accompanied by the sensation of hardness. But by uninstructed minds the colour of the grass and the hardness of the rock are confidently believed to be external phenomena, and not even phenomena of motion at all, but absolutely stationary phenomena in external Nature.

Finally, we must never forget that beliefs in the human mind, whether they be pure or mixed up with errors, can neither control nor even exercise any influence whatever upon what is really taking place in external Nature, which is the object of our investigation. What is really going on in Nature is to be ascertained, so far as it can be ascertained at all, not by projecting human beliefs into external existence, but by applying whatever modicum of dry light we can win from the slow but gradually encroaching progress of scientific discovery. And the necessity for this caution is intensified where we find, as in the present instance, that the belief has resulted from the way our brains and the brains of our ancestors have grown, under the influence of an experience of motion which has been so one-sided that it has never extended to primary motions at all, nor even to any but very coarse forms of secondary motion, omitting, along with many others, all those motions, whether primary or secondary, that occasion most of our sense-perceptions; and all this, combined with suppositions about other phenomena in which these phenomena have been quite misunderstood. Scientific scrutiny, so far as it has penetrated, finds motion throughout external Nature—motions everywhere, motions underlying every phenomenon, however different from motions some of them may seem to common apprehension; and no *scientific* investigation has as yet detected anything but motions. This is the positive side of the inquiry; and its negative side is that it would be manifestly illegitimate to draw an inference about what really exists outside us from the habits of thought which have been engendered in most human minds by a narrow and one-sided experience mixed up with palpable errors. *We, therefore, are not in a position to allege that we know of anything existing in the outer world but motions and relations between motions.*

The abstract of my Royal Institution discourse, which you were so good as to publish, only attempted to give a bare statement of the successive steps of the argument with which it deals, and I fear it is too condensed for clearness; but, as I am myself persuaded that the argument is sound, I hope that your correspondent will find that a fuller account of it which I am preparing will put all its essential parts in a sufficiently distinct light.

Dublin, March 20 G. JOHNSTONE STONEY

[1] Duke of Argyll here employs the word "atom" in its etymological sense; and it is scarcely necessary to point out that the term when so used denotes a different thing from any of the sixty-seven complex bodies known to chemists as chemical atoms, which have intricate internal motions as revealed to us by the spectroscope, and of which the molecules of compound substances are known to be made up. The chemical "atom" could not under any circumstances be spoken of as an *ultimate* particle of matter.

[1] The relations which the parts of motion can have to one another or to other motions are all numerical or space and time relations. Motions may be numerous, few, simultaneous, successive, straight, curved, flat, tortuous, swift, slow, periodic, continuous, linear, or pervading a volume; but they cannot be green motions or hard motions.

Magnetic Disturbance

THERE was a considerable disturbance of the magnetograph recorded here on March 15, and had the photographic curves been developed on that day, we should probably have predicted the occurrence of the aurora seen during the evening. The earth-currents, which are necessary concomitants of magnetic disturbances, were probably intense enough to cause the disarrangement of the cable tests referred to by Mr. Willoughby Smith.

G. M. WHIPPLE

Kew Observatory, Richmond, Surrey, April 7

The Samsams

FROM a note in last week's NATURE it appears that during his recent explorations in the Malay peninsula M. Delouell claims to have discovered the "hitherto unknown" Samsam people. Allow me to state in reply that I have long been aware of the existence of these half-caste Malay and Siamese communities. They will be found duly recorded and described at p. 642 of my ethnological appendix to the "Australasia" of the Stanford Series, published in 1879. They appear to be now mostly Mohammedans, speaking what is called a mixed Siamese and Malay dialect, and otherwise forming an ethnical transition between these two races.

A. H. KEANE

University College, Gower Street, April 4

Meteor

LAST evening (April 3) I saw a fine meteor at 8h. 21m. G.M.T. (± 10m.). I was walking along the street at the time and looking at Algol, and so only caught sight of it during the last few moments of its apparition. Its path as observed was from α 80° North 3 2° to α 76° South 8 4°, when it disappeared behind houses. It seemed quite twice the brightness of Jupiter, and about 3′ diameter; colour, chrome yellow; duration, three seconds. It left no visible train.

H. SADLER

Clapham, April 4

STEEL GUNS[1]

THE whole of this part of the Proceedings of the Naval Institute is occupied by detailed accounts of the steps taken to prepare the way for the establishment of Steel Gun Factories for the United States. We are informed that, while the rest of the world has advanced with the progress of the age, the artillery of the United States has made no step forward. Artillerists and advocates for providing adequate means of defence have laboured under many difficulties during the last twenty years, while regret is expressed that personal interests have entered so largely into the discussion of a question of such magnitude. In the House of Representatives it was declared that the fortifications of that country were in an absolutely worthless condition for all purposes of warfare.

Early in 1882 communications were opened with the owners of the chief foundries and steel works of the United States, but no firm could be found which had ever made steel guns.

At length the President of the United States was authorised and required to select six officers of their army and navy to examine and report respecting the necessary navy-yards and arsenals. Accordingly, the President named six officers (April 2nd, 1883) to form the Board of Gun Foundry, and one of their number, Lieut. W. H. Jaques, U.S.N., was elected secretary to the board. Their report was dated February 16th, 1884. The Board found it necessary to seek information in Europe, and make visits to England, France, and Russia, in order that they might reply satisfactorily to the Act of Congress. There they were well received, and had every facility afforded them in making their inquiries. The aim of Lieut. Jaques, U.S.N., in his communication to the Naval Institute, was to show the necessity of steel gun factories to the United States, to extend the information collected, and to furnish a book of easy reference to the details of modern ordnance. He has produced a work which ought to warn and instruct us.

The Board in their Report give an account of the introduction of the coil system of building up guns in England, of the cost of the system to this nation; of the 100-pounder Armstrong, adopted for the navy in 1859, and of the constructing of one hundred of the 12-pounder before any experiments with them had been concluded.

Of four guns under trial, three showed a separation on the outside between the trunnion ring and the coil below it. The fourth showed a separation all round, but to less extent. All the guns expanded in the shot chamber as part of the powder chamber, and the *bore were elongated*. Much of these defects, no doubt, arose from excessive friction between the lead-coated projectile and the gun, which caused an unnecessary stress upon the gun.

The first visit paid by the Board was to the Elswick works. They remark: "The establishment at Elswick is thoroughly equipped for heavy work, and has produced the largest guns in the world. . . . The shops are supplied with an abundance of fine tools," page 583. They have a hammer of thirty-five tons. "The advantages of the Whitworth manufacture are also recognised, and a hydraulic press is being introduced."

They next visited the Woolwich Royal Gun Factories, which are stated to have had in 1873-4 a capacity for the production of 6,000 tons of guns of various calibre per year. "The transition state in which the Board found the Woolwich gun factories is due to the change from muzzle-loading to breech-loading, and the substitution of homogeneous metal for the wrought coil" (page 590). The Board give a list of the chief tools in the Arsenal, as boring machines, planing machines, &c. There are also travelling cranes of 60 tons, six of 30, and six of small capacity. There are also: one steam hammer of 6 tons, one of 12 tons, one of 10 tons, two of 7 tons, besides many smaller ones. The steam power in the Royal Gun Factories is supplied by forty boilers of 40-horse power. "The plant at Woolwich, because of its wasteful methods, contains very little worthy of imitation in planning the erection of gun factories in the United States."

The Board next visited the works of T. Firth & Sons, Sir John Brown & Co., C. Cammell & Co., and Sir H. Bessemer, all of Sheffield, and Lieut. Jaques gives full accounts of the most recent furnaces and methods employed there in working steel, illustrated with many useful plates. He also gives an account of the manufacture of compound armour, under the patents of Wilson & Hadfield, as well as of the trials of armour plate made at Spezzia and of granite forts protected by iron plates at Shoeburyness in 1883.

"The new departure in the system of gun construction, described further on in this report, will demand from the Sheffield steel manufacturers increased effort. Up to the present time the only portion in the construction of the Woolwich gun that required steel was the tube. . . . The new construction requires that steel shall be used throughout, and the castings for the jackets for guns now on hand at Woolwich can hardly be supplied from Sheffield" (page 630).

It is remarked that in one important establishment preparations were being made for the introduction of a large press, to take the place, or supplement the work of the hammer. The Sheffield steel manufacturers are entirely sceptical as to the advantage or practicability of the compression of steel in the liquid state, and although they concede the efficacy of forging under hydraulic compression, they consider it an objection to the process that a much higher temperature will be required for the press than for the hammer.

Sir Joseph Whitworth's works at Manchester and

[1] Proceedings of the United States Naval Institute, vol. x. No. 4, 1884. "On Establishment of Steel Gun Factories in the United States," by Lieut. W. Jaques, U.S.N.)

ed, where they enjoyed the privilege of carrying on
investigations within the works. "It may be dis-
dly asserted that the experiences enjoyed by the Board
ng its visit amounted to a revelation" (page 633).
The distinguishing characteristics of the Whitworth
l-compressed steel are homogeneity, strength, and
ility. It is made of various tempers to suit all pur-
es, particularly where it is exposed to sudden and
ent strains. . . . No other metal possesses the same
rance" (page 633). Sir Joseph Whitworth is said
ave remarked that, "Guns of enormous size are now
g made at Woolwich at an enormous expenditure. . . .
if monster guns were wanted, they could be made at
less cost by means of the Siemens-Martin process and
l compression. Supposing a hoop was wanted, say,
ons weight, the time required for its production would
commencing with the raw material, he believes, be
e than one-tenth the time required by the forging, coil-
and welding processes. . . . The Board witnessed the
rations of casting followed by that of liquid compres-
, the enlarging of hoops, the drawing out of cylinders,
the forging of a solid ingot. The unanimous opinion
he members is that the system of Sir Joseph Whit-
th surpasses all other methods of forging, and that it
s better promise than any other of securing that
ormity so indispensable in good gun metal" (page
).
France, as in England, the most friendly welcomes
e tendered to the Board. The Government has ob-
ed an immense increase of its resources by encouraging
ate industries. The foundry at Ruelle has become the
cipal, if not the only, establishment for the manu-
ure of the larger calibres designed for the navy and
.
It contains the most remarkable collection of tools of
ge. They are designed for guns of 34 cm. (13·4 in.)
upwards, and have a capacity for handling guns of
tons in weight and 60 feet in length" (page 638).
It seems as if in France the happy mean has been
hed by which the Government and the private indus-
can work harmoniously towards the accomplishment
national object. In a combined system of this kind,
very important to be assured that there exist mutual
ks which act to prevent one party imposing improper
rd terms on the other" (page 639).
r tubes and hoops for large guns the supply is limited
he works at St. Chamond and at Le Creusot; the
er having a steam hammer of 80 tons and the latter,
of 100 tons. At Le Creusot are situated the most
rtant steel-works in France. "At no other place in
world is steel handled in such masses, and it is safe
y that no proposed work can be of such magnitude
exceed the resources of the establishment" (page
. There is assembled an array of steam hammers not
lled in the world. They have three cranes capable of
ining 100 tons, and one 160 tons. For the prepara-
of metal for cannon and armour-plates Le Creusot is
roughly equipped.
ittle need be said of Germany, as that country depends
st entirely upon Krupp's establishment for the supply
guns, and the Board were not allowed to examine
orks, for they were informed that the works at Essen
ot be seen, as "these are closed to all but those who
special business of inspection of war material on
." Krupp enjoys great advantages in having practice-
rounds at Meppen 104 miles long, and at Dülmen 16
iles. Near thirty years ago Krupp planned his 50-ton
mer. He is constructing a 121-ton 16-inch gun of
ilibres length for the Italian Government.
e Russians formerly patronised Krupp, but of late
have begun to manufacture guns at home, with the
ances of private firms. Like many of the great steel-
s of Europe, the establishment at Aboukhoff is in a
tion at once. They possess ten steam hammers, vary-

ing from a 1-ton to a 50-ton. The most important improvement which has recently been introduced is Sir J. Whitworth's system of liquid compression.

Certain recommendations are made respecting the production of guns for the United States. As examples of a practical partnership between a Government and a private company, in working towards a national object, the experiences in England and Russia are very instructive, and warn against the adoption of such a system. As an example of depending almost entirely on private works, Germany is a perfect instance. As an example of depending alone on Government works France was a perfect instance before the Franco-German war. "How entirely France has now altered her system is shown in a previous part of this report; her present practice is theoretically perfect, and it has proved to be practically efficient. Her Government establishments are still retained, but as gun factories simply, in which the parts are machined and assembled, but for foundry work she depends upon the private industries of the country" (page 843). But still the Government is careful to secure good advice in controlling these private establishments, for on one occasion it was considered desirable to require the steel to be supplied to be subjected to additional tests. When the steel manufacturers at home resisted this the Government gave the contract to a foreign firm which was willing to comply with their requirements.

An inquiry, instituted in 1882, showed that the cost of steel construction in Europe was then as follows:—Krupp, 51 to 60 cents (26*d.* to 30*d.*) per pound; Whitworth, 38 cents (19*d.*) per pound; Woolwich guns, 30½ cents (15*d.*) per pound; Land service guns (France) 48 cents (24*d.*) per pound; but, it is added, the price of French construction has been greatly reduced (page 852).

From the short extracts we have been able to give from this most important and instructive work it must be apparent that the private firms in Germany and France are much in advance of those in England in respect of the magnitude of the steel-works they are able to execute, but only in consequence of Government encouragement and patronage. There are in those countries steam hammers in operation of at least double the weight of any in use in this country. And yet, it must be remarked, these hammers are of English invention, and that the best armour-plates manufactured on the continent are made according to an English patent. The Bessemer process and the Siemens furnace are there much used. But it is equally plain that we have at Manchester and Sheffield several firms capable of successfully competing with the world, if they receive that support which a Government only can give.

After the failure of the 110-pounder B.L. Armstrong gun above noticed, it is remarkable how suddenly the system was abandoned. It was quite plain that the evil arose from the obstruction to the initial motion of the shot, and from the enormous friction all along the bore. But there seems to have been no real effort made to remedy this evil. If the lead coating did not prove satisfactory, why not rifle a condemned gun on the shunt principle and try studded shot? The original B.L. guns seem to have been much better proportioned guns than the M.L. guns which superseded them, for in a lecture delivered before the Royal United Service Institution about 1873, it is remarked that "A long B.L. 40-pounder converted into a M.L. 47-pounder is remarkable for the small amount of resistance it gives, and for its great accuracy of fire. . . . The regularity of the resistance of the air is also very remarkable," *i.e.*, when compared with the shooting of service M.L. guns of the same date. There is no known reason why this gun shot so well, except from its extra length. But the hint was not attended to. And the shortness of the English M.L. guns has been often remarked. Thus at the famous contest at Tegel, in 1868, between a 9-inch 12½-ton M.L. "Woolwich" gun coming

£1,500 and a Krupp 9½-inch B.L. gun of 14½ tons costing £3,453, the length of the former was 125·5 inches and that of the latter 157·6 inches. Great complaints were justly made of the unfairness of the comparative trial, because, while the English gun was strictly confined to service conditions, the German gun was repaired and altered so that every feature of the original combination was changed. After some months' delay Krupp raised the initial velocity of his gun from 1,115·3 f.s. to 1,286 or 1,414 f.s., according to whether a 330 lb. shot or a 275 lb. shell was used. Time has now decided this contest. Here we remark how ready Krupp's party were to notice defects and apply remedies. If the English party were debarred from effecting improvements at Tegel, they were free to improve at home. They had seen that it was possible to construct a 9½-inch B.L. gun, firing lead-coated projectiles, which could compete with an English 9-inch M.L. gun. But we do not hear of any further attempts having been made to render the 110-pounder (about 7 inch) B.L. Armstrong gun an efficient weapon.

Last spring we were informed by authority that the new B.L. gun then about to be constructed would be *double the length* of the old B.L. gun. And quite recently the *Times* intimates a doubt about some newly constructed guns having sufficient strength in front of the trunnions to resist the full charge for which they were constructed. Now some years ago we heard a good deal about the doings of a Committee on Explosives, which carried on experiments for several years, and at last reported. What could be the use of such a committee if it did not furnish rules for *properly proportioning the strength* of guns, and for determining the *proper length* of bore required for the profitable consumption of charges of slow-burning powder? Although Rodman and the pressure gauges and chronoscopes appear to have failed to give reliable results, it would not be difficult to contrive experiments which would give the practical value of every inch in length of the bore, and at the same time show the effect of great length of bore upon the steadiness of the motion of the elongated projectile.

In October, 1883, it was stated in the papers that some comparative trials had been made at Portsmouth before "my lords," between a Krupp and an English 6-inch B.L. gun, "greatly to the advantage of the former." A Krupp gun fired a 64 lb. shot with a 14 lb. charge and the English gun a 100 lb. shot with a 34 lb. charge. That is, the charge of the Krupp gun was two-ninths, and that of the English gun three-ninths of the weight of its shot. This increased charge might be a positive disadvantage to the English gun if it was a short one. This is a case requiring the most careful and candid investigation. Any fine morning a thorough comparison of the performances of these two guns might be carried out in a searching manner, if only known means of doing this were employed. In order to succeed in gun-making it is absolutely necessary for careful experiments to be carried out to clear up anomalies, such as we have mentioned.

This work is illustrated by seventy-eight most carefully executed plates of guns, carriages, large steam hammers, and cranes, furnaces, plans of works, &c., and it concludes with estimates of the expenses of equipping a gun foundry according to modern requirements. F. B.

ON THE FORMATION OF SNOW CRYSTALS FROM FOG ON BEN NEVIS

IN addition to the actual fall of snow, hail, &c., there is on Ben Nevis a form of solid precipitation scarcely known on lower ground, but of almost daily occurrence here. In ordinary weather the top of the hill is enveloped in drifting fog, and when the temperature of the air and ground is below freezing this fog deposits small crystalline particles of ice on every surface that obstructs its passage. These particles on a wall or large sloping surface, as described in a recent letter in NATURE (vol. xxx. p. 29 combine to form long feathery crystals; but on a post similar small body they take a shape more like fir-cones with the point to windward. Whether this deposition from the vapour of the fog directly or from actual particles of frozen water carried along in it is not very clear. The forms and arrangements of the crystals vary according to the form of the surface to which they adhere, but all belong to this feathery or cone type, the branches lying at an angle of 30° with the main axis pointing to windward. They are formed wherever the wind blows past an obstructing body. On a flat board they gather thick and most abundantly near its edges, forming a white beautiful border around it; while the centre, which I suppose the wind does not directly reach, remains clear. A round post, on the contrary, has an almost uniform coat of these crystals all over its windward half, and so accurately do they point to windward that it is possible to trace changes in the direction of the wind from the successive layers of crystals lying at different angles. The rate of growth varies with the density of the fog and the speed of the wind, but for the ordinary winds and fogs of this exposed position about half an inch per hour may be taken as a rough average. I have never seen it exceed two inches per hour. If there is a damp feeling in the air, if in fact it is mist that is passing rather than fog, the crystals are icy and hard; but when the temperature is well below freezing and the fog feels comparatively dry, they are looser in texture, seem when first formed to be attached by a mere point to whatever they are on, and are pretty easily knocked off. There is practically no limit to their growth; last winter during a long continuance of strong south-westerly winds and very cold weather a post 4 inches square grew into a slab of snow some 5 feet broad and 1 foot thick in less than a week. The crystalline mass then fell off by its own weight and a new set began to form.

The effect of this growth on all the instruments exposed to its action may be easily imagined. Nothing keeps its shape or colour. The louvres of the Stevenson's screen for the thermometers become serrated with rows of teeth which quickly coalesce into a solid mass completely stopping any circulation of air inside the box. The use of exposed radiation thermometers, black bulb in vacuum, &c., is rendered well nigh impossible, as these delicate glass instruments would run serious risk of breakage in clearing them of the deposit, while their readings would have little value, being merely the record of the temperature inside a more or less opaque mass of snow. Very often the rain-gauge is coated with these crystals an inch thick on its windward side, while not a particle is to be seen inside. Ordinary anemometers of the type of Dr. Robinson's cup instrument become useless: the cups are no longer hemispheres, but irregular hollow bodies bristling all over with pointed crystals, and the arms carrying them increase to many times their original thickness, thus offering much greater surface for the wind to act on. Under such circumstances the anemometer at the Observatory is usually left to its own devices, and grows into an irregular mass of snow scarcely showing any trace of its original outline, to be cleared again when dry weather or a thaw gives it a chance of working. When the fog comes on while the anemometer is still turning, the crystals form chiefly on the outside of the cups and arms at their edges, leaving the insides pretty clear. The arms carrying the cups get completely covered, and on the diagonal stays supporting the arms the crystals show a beautiful "twined" structure pointing downwards and outwards on each side.

Occasionally the crystals are smoky-brown in colour instead of white. For example, those found on December 23, 1884, were distinctly brown, but on the 24th they were overlaid by a pure white set. What causes the

age of colour and whether it is connected with any ial state of the weather I have not yet determined.

ote.—Since the above was written, I have made a gh attempt to measure definitely the rate of growth of e crystals. A cylindrical stoneware bottle 3·6 inches and 2·25 inches diameter was stuck upside down on st 40 inches high for three hours at a time, the crys- formed on it melted down and the volume of the water sured. Assuming that the cylinder acted like a flat ace placed perpendicularly to the wind whose height breadth are equal to its height and diameter—an umption that appears to be very nearly true, at least mall surfaces—I find that with dense fog and strong 8 (force 6 to 8 of Beaufort's scale) the rate of growth, measured above, is about 0·125 inch per hour. That is ay, if the density of the snow be one-tenth that of the er, the crystals were growing at the rate of one and a rter inch per hour. The crystals were quite loose feathery, and contained practically no fallen or ed snow; all had been formed directly out of the

BIRD ARCHITECTURE

HE way in which a bird builds its nest, seemingly without instruction, thought, or experience, has been atedly brought forward as a convincing proof of blind llible instinct governing it in its task. No more ular proof has been brought forward by the supporters ie blind instinct theory than that of bird-architecture. thought a wonderful thing for a bird to build a nest tout any instruction, or without ever seeing a nest cal of its species. That birds are capable of such vellous powers has long ago been denied by Mr. llace, and we have not a particle of evidence that such eally the case ("Nat. Selection," and Seebohm's it. B.," ii. Introd.). Indeed the evidence, such as we glean, goes far to disprove the presence of any such inctive power. Birds brought up in confinement have found not to make a nest typical of their species, generally content themselves with forming a rudi- itary structure—heaping a lot of material together tout any design, or even laying their eggs on the bare nd with no provision at all! In my opinion, how- , the conditions of life are so changed when a bird is in confinement that too much weight should not be ched to its actions in captivity, and the experiment never to my knowledge fairly been tried with wild ls or birds living under normal conditions.

remarkable instance, however, of a changed mode of -building has just been brought to my notice by Mr. Burton, the well-known naturalist of Wardour Street. ie time ago his brother (now employed at the museum Wellington, N.Z.) took out to New Zealand a number oung birds of our common native species, with the ct of introducing them to the Antipodes. Amongst n were some young chaffinches (*Fringilla cælebs*). se were turned out and have thriven well in a state, bidding fair to permanently establish this rming little bird in our distant colonies. Some of the ls have built a nest; and to Mr. Burton I am indebted a photograph of the wonderful structure they have en. It is evidently built in the fork of a branch, and ws very little of that neatness of fabrication for which bird is noted in England. The materials with which made seem very different, too. The cup of the nest small, loosely put together, apparently lined with hers, and the walls of the structure are prolonged for at eighteen inches, and hang loosely down the side of supporting branch. The whole structure bears some mblance to the nests of the Hangnests (Icteridæ), with exception that the cavity containing the eggs is situ- l on the top. Clearly these New Zealand chaffinches e at a loss for a design when fabricating their nest. They had no standard to work by, no nests of their own kind to copy, no older birds to give them any instruction, and the result is the abnormal structure I have just described. Perhaps these chaffinches imitated in some degree the nest of some New Zealand species; or it may be that the few resemblances this extraordinary structure presents to the typical nest of the Palæarctic chaffinch are the results of memory—the dim remembrance of the nest in which they had been reared, but which had almost been effaced by novel surroundings and changed conditions of life. Any way we have here, at last, a most interesting and convincing proof that birds do not make their nests by blind instinct, but by imitating the nest in which they were reared, aided largely by rudimentary reason and by memory. I have not the least doubt that, had these young chaffinches been *hatched* in an alien nest in this country, and never allowed to see a nest typical of their species, or have any connection with old and experienced birds, the results would have been still more startling and strange. Man has to *learn* the particular art of house-building practised by his own peculiar race—birds have to do the same!

CHARLES DIXON

THE INSTITUTION OF NAVAL ARCHITECTS

THE Annual Meetings of the Institution of Naval Architects were held during the week preceding Easter at the rooms of the Society of Arts. There were five sittings, at which the necessary routine business was transacted, the presidential address of Lord Ravensworth was delivered, and seventeen papers were read and discussed. On the whole the meetings were successful and the papers of good quality, but far too much work was attempted in the time available. It is to be hoped that the growing importance of the proceedings and the improving financial position of the Institution may lead the Executive to arrange for holding regular autumnal sessions at the principal outports, in addition to the spring sessions in London.

The papers read were chiefly "papers of information," having a strictly practical or descriptive character, only two or three having scientific pretensions. Marine engineering also occupied a far more prominent place than has been usual hitherto, nearly one-half of the papers having relation to the propelling apparatus of steamships. The fact is significant, indicating the remarkable progress which has recently been made in marine engineering, and suggesting the progress which may yet be made. Of the papers coming into this group, that by Mr. Macfarlane Gray, of the Board of Trade, was the only one of a scientific nature. Mr. Gray has on more than one occasion brought his "ether-pressure" theory before the Physical Society, where it has not been well received. His recent paper "On the Theoretical Duty of Heat in the Steam-Engine" was probably understood by only a few of his hearers; and Prof. Cotterill, whose authority on the subject is undoubted, was the only speaker who really contributed any useful criticism. While complimenting Mr. Gray on some of his graphic processes, and expressing admiration for his courage and perseverance, Prof. Cotterill took exception to the generalisations attempted in the paper and to the assumption that the results so far obtained were any real confirmation of the soundness of the theory advanced.

All the other engineering papers were of a practical character. The actual performances of "triple-expansion" engines as compared with the "double-expansion" or ordinary compound marine engines, were discussed at length. Experience appears to be conclusive on the point that, by using steam of 120 to 150 pounds' pressure, and having three successive expansions in separate cylinders, an economy of from 15 to 20 per cent. in coal consumption is to be realised. This economy is of the highest importance, both in mercantile and war ships;

and on long ocean voyages its effects are felt, not merely in the lessened expenditure of coal, but in the gain in cargo-carrying capacity. Twenty-five years ago an expenditure of from 4 to 6 pounds of coal per indicated horse-power per hour was considered good engineering practice. By the introduction of surface-condensers the expenditure was reduced to about 3 to 4 pounds; by the use of the compound engine with higher steam pressures the expenditure fell to about 2 to 2½ pounds; and now with triple expansion it has been brought nearly to 1½ pounds, or less than one-third of the rate common a quarter of a century ago. These are results of which marine engineers may be proud, and which make the extended use of steamships certain. Nor is further progress to be doubted. Much remains to be done in improving the marine boiler, and Mr. Milton's thoughtful paper on the subject will do good. Attention has been so fixed on the economical use of steam in the engines, that the possible gains by improvements on the generators of the steam have been overlooked to some extend. The employment of "forced draught" in the stokeholes is becoming so common, that it was to be expected that a discussion would arise upon it. Mr. Robinson read a paper describing a method by which steam yachts might have the combustion quickened by driving air under pressure into the furnaces, but not closing in the stokeholes as is done in torpedo boats. This paper was not merely interesting in itself, but served the useful purpose of calling forth some valuable statements of experience gained on larger ships. Forced draughts with closed stoke-holes is now becoming a recognised feature in war-ship design. By these arrangements, involving very moderate additions of weight and cost, the indicated horse-power can be increased by from 50 to 60 per cent. above that obtained with natural draught, and the "forcing" of the combustion can be carried on for four or five hours. A very considerable gain of speed is thus possible for a moderate time, and under ordinary working conditions with low speed, the economical expenditure of fuel is possible. In special types of merchant ships forced draught would also prove of great value; and even in sea-going steamers something of the kind is likely to be done. Trials are already in progress which promise a great economy in the weight and space required for the steam boilers, while preserving economy in coal consumption. A paper by Mr. Linington, of the Admiralty, on the propelling machinery of high-speed ships, gave a considerable amount of information as to recent Admiralty practice; and another paper by Mr. Joy, described a special arrangement of valve gear adapted for quick-running engines. Upon the efficient working of such gear, and the proper distribution of the steam, very much depends when high piston speeds are accepted, and the weight of machinery reduced.

Mr. Thornycroft's name will always be associated with the introduction of the modern torpedo boat, in which quick running engines of remarkable lightness in proportion to their power are fitted. His paper on a special form of screw propeller suitable for vessels of very shallow draught and relatively high speed naturally attracted great attention. The fundamental principle of this propeller is not a novelty; but Mr. Thornycroft has brought to a practically successful form what has been little more than an experiment in the hands of others. The propeller is one which works with a large amount of "slip," but it is associated with a system of fixed "guide-blades" and casings, by means of which the momentum of the water in the propeller race, which would otherwise be wasted, is made to contribute effectively to the forward thrust of the propeller. The net result of the arrangement is that for a given total weight of propelling apparatus a higher speed can be obtained than is possible with any other propeller yet tried in shallow draught vessels.

Mr. Parker, of Lloyd's, read a paper on the use of thick steel plates for boilers carrying high pressures of steam, with special reference to a case of recent occurrence where a plate fractured badly and in a most unexpected manner. This paper gave rise to one of the most lengthy and interesting discussions at the meetings. Steel makers and users of steel mutually benefit by the joint examination of such problems, which will probably become more frequent than they now are as the manufacture advances. The general opinion expressed in the discussion was distinctly in favour of the generally good behaviour of the new material, whose superior strength, ductility and homogeneity make it so formidable a rival to the best brands of iron.

Two papers on riveted joints were well received, the first giving a *résumé* of recent Admiralty experiments on riveted specimens of steel shipwork; and the other dealing with certain points of importance in the making of boiler shells.

Amongst the remaining papers, one, dealing with the stowage of steamships, contained a mass of valuable facts. Another paper dealt with the possibility of means such a disposition of the coal bunkers in steamships as the consumption of the coal might not prejudice the stability or render large quantities of ballast necessary. A third was a scientific attempt to lay down rules for competitive yacht-rocking—a hopeless task we fear.

There still remain to be noticed three of the most important papers in which a distinctly scientific method was followed. Undoubtedly the best of these, from the scientific point of view, was that contributed by Mr. Froude, in which he examined into the remarkable effects of the free water may produce in checking the rolling motion of even the largest ships. Mr. R. E. Froude assisted greatly in the investigation, and exhibited a model in which the behaviour and influence of the free water were admirably illustrated. It seems obvious that by this means the greater steadiness at sea may be insured than is possible with bilge keels or other appliances of that kind. But there is a need for scientific treatment in order to secure the best steadying effects in a safe and practical form.

Another excellent paper was that on "A Mechanical Method of Measuring a Vessel's Stability," by Mr. Reed. Here also a model was used, and by a very ingenious device the movements of the centre of buoyancy of the ship represented by the model were accurately and easily determined for all angles of inclination. It is a method which can be used by comparatively unskilled assistants in a drawing office, although its invention is a great thorough knowledge of the principles of stability on the part of the inventor. The plan ought to be widely and doubtless will be.

Finally, reference must be made to the only paper contributed by a naval officer, Capt. Noel, in which he attempted to lay down rules of general application for measuring the "fighting efficiences" of war-ships of all classes and sizes, differentiating their values according to the nature of their speeds, manœuvring powers, armaments, protection, seaworthiness, and other qualities. The task is seemingly a hopeless one, and no general rules can apply. At the same time the paper sets out clearly and succinctly the leading characteristics on which fighting efficiency depends, and in that sense will be of service to the Institution.

W. H. W.

THE EGGS OF FISHES.[1]

CONSIDERABLE advances within comparatively recent times having been made in regard to our knowledge of the spawning of fishes, and the treatment of

[1] Introductory Lecture delivered to the Class of Natural History in the University of St. Andrews, on November [illegible], by [illegible], F.R.S.

eggs after deposition, I have selected this subject
introductory lecture, since some opportunities have
been afforded for its investigation in our own
. These facilities have occurred at sea in con-
n with the Trawling Commission, and on land
e Marine Laboratory—now, I am glad to say,
ished, by the aid of the Scotch Fishery Board,
easy reach of the students of Natural History in
niversity.
subject, moreover, is one of general interest, for it
a short time since works devoted to the history of
fishes were devoid of allusion to any other mode
wning than that by which the eggs of our marine
were deposited on the bottom of the sea. Indeed,
believed by most naturalists that the latter was the
l mode of deposition. As a consequence, some of
ct-books at present in use either follow the latter
or do not specially allude to the question. Under
circumstances, it is not surprising that the majority
se who have spent their lives from boyhood onward
pursuit of line-fishing should maintain, even at this
nt, that the eggs of all marine fishes are deposited
bottom of the sea—with a tenacity all the more
ient as several apparent corroborations by experi-
(which they had, with praiseworthy interest, made,
hich I shall allude to by and by) seemed to justify
pinion.
e eggs of all fishes are produced in the ovaries—
etrical organs which lie beneath the vertebral
n, and which at different periods of the year present
s appearances according to the degree of develop-
of the eggs. Thus in the quiescent condition of the
s, as in the case of the green cod before you, their
s insignificant, while the fully-developed ovaries
y a large space and weigh several pounds. At first
gs are very small, but they gradually increase in
y imbibing nourishment from the ovarian follicles in
they are placed.
eature not sufficiently insisted on in our country is
t that only a portion of the ovary in most marine
becomes "ripe" at a given time, the matured eggs
g along the oviduct and escaping externally. This
ion appears to be admirably suited for the increase
fishes, a constant succession of embryos being thus
ed, and time afforded for those of one stage to dis-
r, as we shall afterwards see, from the surface of the
before those of the succeeding take their places.
erica this condition has been clearly described in
eport on the cod-fisheries of Cape Ann, by Mr.
for the United States Fish Commission in 1880;
ie account does not seem to have come under the
of Mr. Oldham Chambers, who alluded to the
a year or two afterwards.' Mr. Farll observes
e individuals (*i.e.* the cod) do not deposit all their
n a single day or week, but probably continue the
tion of spawning over fully two months. The result
s arrangement is that the American cod begin to
in September, and some continue as late as June.
od in our own seas do not follow the same habit,
h their spawning-period extends on each side of the
ning of April. In the same way the period during
the eggs of the various kinds of skate are deposited
siderably lengthened.
the other hand, such marine fishes as the lump-
and bimaculated sucker, the salmon, trout, and
freshwater fishes seem to deposit their eggs within
mited period of a day or two, and consequently the
portion of the masses of eggs in the ovar
simultaneous.
importance of this point in the history
es will be apparent when it is viewed in
close time in legislation; for while no

be more simple than the fixing of such a period in the case of the salmon, which spawns in rivers, it would be very different in the case of such as the cod, sole, and turbot, both on account of the lengthened and diverse periods in each case, and the vastness of the field in which it is to be applied.

In general form the eggs of ordinary fishes are circular. On deposition they are usually invested by a single layer (zona radiata), though in some, as in the herring, there is another, viz. the vitelline membrane, which lies outside the former. The great mass of the egg is formed by the oval spherules of the food-yolk, which are separated by protoplasmic bands. Near one of the poles the protoplasm usually forms a lenticular area, the germinal disk or germinal area, and the smaller yolk-spherules in this region differ in character from those of the general mass of the egg. During development the eggs show partial segmentation, this process being chiefly confined to the germinal area.

While the circular form as just described is characteristic of the eggs of most fishes, we have a few marine types which deviate from the general rule, *e.g. Myxine* (glutinous hag), with its ovoid and fringed eggs, the goby, with its fusiform ova, the gar-pike, saury pike and flying-fish, which have long filaments attached to their eggs—probably for the purpose of fixing them to floating structures of any kind. Amongst other interesting types are the large eggs of the stickleback and the salmon-tribe, and the almost microscopic eggs of the eel. The large ova of the salmon and trout are surpassed, however, by those of the Siluroid genus *Arius*—found both in the Old World and the New (Ceylon and Guiana)—the eggs being somewhat larger than a pea (5-10 mm.): but this is not the only remarkable feature in these fishes, for, as Drs. Günther and Wyman and Prof. Turner have shown, the large eggs are carried by the male in his mouth and gill-chamber until hatched, the small and almost granular palatine teeth making this possible, without injury to the ova. He thus acts the part of a dry nurse, as also does the male pipe-fish (*Syngnathus*), and the sea-horse (*Hippocampus*), the eggs being borne by the male in a pouch on the under surface. In another Siluroid fish (*Aspredo*) from Guiana the remarkable exception occurs of a female fish interesting itself in the care of its young. The skin on the under surface becomes soft and spongy, and the eggs, which are deposited on the ground, adhere by simple pressure of the body over them—very much after the arrangement in the Surinam toad. Only one other female fish shares with this one the distinction just noted, viz. *Solenostoma*, an Indian Lophobranch, in which the ventral fins (free in the male) coalesce to form with the integuments a pouch for the reception and hatching of the eggs. The entire group of the sharks and rays (Elasmobranchs), again, is characterised by the peculiar condition of their eggs, which are not only distinguished by their great size, but by the fact that they are either deposited in horny capsules, or retained in the oviduct until hatched. The former takes place in the common rays, certain dog-fishes (*Scyllium*), and sharks (*Cestracion*), and in the curious *Chimæra* and *Callorhynchus*; while the latter, that is the production of living young, occurs in the rest of the sharks and in *Torpedo*.

As already indicated, the prevalent notion amongst the older naturalists was that fishes of all kinds deposited their eggs on the bottom of the sea, and that extensive migrations were made by various kinds for this purpose, the general impression being that the majority proceeded
wards to deposit their eggs in the shallow water.
ion was probably due to the fact that the
erhaps the herring, followed this habit, the
ong up rivers, and the latter selecting
anks (often near land) covered with sea-
ses, or a bottom composed of stones
ing their opinions on these facts, it was

assumed by the older observers that all marine fishes followed similar habits. Thus it was supposed that the cod, haddock, whiting, ling, hake, and other fishes frequented certain banks for the purpose of depositing their eggs, and that various flat fishes, such as the larger examples of turbot and sole, came from deep water to shallow water for the same end. Such conjectures, however, were found to deviate very considerably from the actual condition.

Amongst the earliest to notice that the eggs of certain marine fishes floated were the cod-fishermen of the Lofoden Islands, off the coast of Norway. These Norwegians had noticed that what they called the "roe" of the cod-fish floated in the water on the great fishing-banks, and often at certain seasons to such an extent as to make the water thick. Prof. G. O. Sars, Inspector of Fisheries in Norway, to whom this remark was made, supposed that the fishermen had mistaken some of the lower marine animals for the eggs of fishes, for such a feature was in direct opposition to anything he knew of the spawning of fishes. The subject, however, was soon set at rest, for he proceeded in 1864 to the fishing-grounds above-mentioned, viz. off the Lofoden Islands, and captured in the tow-net immense numbers of the eggs of the cod floating at the surface of the sea. Next year, indeed, on a calm day, Prof. Sars found the sea covered with a dense layer of floating spawn, so that with a sufficiently large net he could have taken tons of it. This occurred over a celebrated fishing-ground, on which the cod were present in enormous numbers, so as to form what the fishermen called a "fish mountain." Sars also found that the ova of the haddock floated, and amongst the eggs procured from the surface of the sea were some from which young fishes resembling gurnards emerged, and he correctly concluded that the ova of the gurnard followed the same habit as those of the cod and haddock.

The impetus given to such observations by the energetic action of the United States Fish Commission enabled the Americans to corroborate the discovery of the Norwegians in regard to the floating of the ova of the cod, which lately have been artificially hatched on a somewhat extensive scale on their coasts. The labours of the distinguished Prof. Alex. Agassiz in the same country have further added to our knowledge of floating eggs, so that the number of fishes in which this occurs is considerable. Thus the majority of the American flounders, certain kinds of wrasses (*Ctenolabrus*), a species of sparling (*Osmerus*), several species of cottus, cod, haddock, gurnard, shad, mackerel, and Spanish mackerel, a kind of dory (*Zeus*), and the frog-fish are amongst those which have floating eggs. The late Dr. Malm of Gothenburg further increased the list by discovering that the eggs of the plaice were similarly buoyant; and G. Brook has recently added to this category the eggs of the lesser weever. The very great influence which this floating of the tiny eggs exercises on the multiplication of the food fishes will be apparent as we proceed.

On the other hand, most freshwater fishes (except the shad) deposit their eggs on the bottom like the salmon, or on water-plants, like the carp and pike; while other marine species, such as the herring, sprat, lump-sucker, and bimaculated sucker, follow a similar method. The number of marine fishes which are supposed to deposit their eggs on the sea-bed is yearly diminishing, while the ranks of those in which the ripe eggs are found to float correspondingly increases.

To come now to our own shores, and to confine our remarks to what is really the most important group of fishes, viz. the food-fishes, we find that early in spring the surface of the sea over the great fishing-banks, such as Smith Bank, off the north-east of Scotland (Caithness), presents vast numbers of floating eggs of food-fishes, together with multitudes of the very young fishes provided with a yolk-sac exhibiting various degrees of absorption. Some of the ova (*e.g.* those of the haddock and gurnard) are larger than those of the cod, but they are few in number, while a fourth kind are smaller than any yet mentioned. When placed in a vessel of sea-water the eggs generally float on its surface, descending but a very little even if the jar is rudely shaken. Even after a protracted period only the dead eggs roll on the bottom of the vessel, as the floating eggs are living. Moreover, the eggs may be removed from the cod itself, and carried from Scotland to the Marine Laboratory at the harbour. On arrival these floated at the surface of the vessel. On transferring them to a larger jar and turning on a tap of sea-water a great change occurred. The ova in a few minutes sank on the bottom. Microscopic examination subsequently showed that the edge of the germinal area was disintegrating—free protoplasmic processes and separate cells occurring all round. The cause of this sudden change was doubtless the impurity of the water (for the proper apparatus had not yet been fitted up), the metallic pipe (block-tin) containing an opaque whitish deposit which speedily killed the ova. The addition of methylated spirit in the same way sends all the eggs and embryos to the bottom. Sars, indeed, mentions that if the eggs of the cod are placed in fresh water they sink, and never rise again. They are killed—just as a newly-hatched salmon is killed—though somewhat more slowly, by immersion in sea-water. Sars thinks that even a fall of rain would affect the floating of the ova in the sea, but this is unlikely.

More than once the eggs of the haddock and other fishes have been brought under notice as lying on the bottom of a vessel, and therefore held as proving that the ova did not float. But in every case such eggs were found to be dead or dying, unripe, or not even fertilised. If in removing the eggs from a fish, too much pressure is applied, unripe eggs escape. Such either are or are not ambiguously, according to the stage of development. Unless this fact is borne in mind, disappointment inevitably occurs, especially to one who has triumphantly vaunted such eggs from deep-sea fishing to vindicate statements that have been impugned. No one ever asserted that dead eggs floated. It is the ripe and living eggs that are so buoyant.

In the Marine Laboratory it has happened that many living ova of the cod rolled on the bottom of the vessel, but this was clearly due to the attachment of fine particles of mud and sand which had gained admission by imperfections in the temporary apparatus, and which surely and speedily in every case proved fatal to the embryo.

The ova and embryos brought from the surface of the sea are comparatively hardy, even though kept for days without renewal of the sea-water. The lively young cod, about 5 mm. in length, with their characteristic black pigment-patches, swam actively at the surface of the water, darting hither and thither when interfered with, while a stratum of the dead lay at the bottom. The water may even be somewhat milky and the odour characteristic, and yet the embryos survive—until, as Sars also has noted, the yolk-sac, which supplies them with nourishment, is absorbed.

The difference between the larval cod and the young salmon just hatched is striking. The former (that is, the young cod) is in a very rudimentary condition, not only in size, but in structure. For instance, the heart pulsates, but, as my colleague, Prof. Pettigrew, observed, there is no visible blood and no blood-vessels. Those, therefore, who say that the heart in animals contracts from the stimulus of its living blood, would here find little support. On the other hand, the newly-hatched salmon has attained great complexity; indeed, several days may be spent in delineating its elaborate blood-vessels alone.

(*To be continued.*)

NOTES

WE regret to learn of the death, at the age of eighty years, the eminent physiologist, Prof. Karl von Siebold, of Munich.

WE have also to announce the death of Mr. Frederick Field, R.S. Mr. Field was one of the original members of the emical Society. He held for some time the post of Vice-nsul in Caldera, Chili, and was successively Professor of emistry at St. Mary's Hospital and the London Institution. : was senior partner of the firm of J. C. and J. Field at the ıe of his death. Mr. Field contributed numerous papers to ious branches of chemistry, especially that relating to the neralogy and metallurgy of South America.

A COMMUNICATION dated March 7 has been received from r. Thorlacius, observer for the Scottish Meteorological Society Stykkisholm, in which he states that till February the winter Iceland was not a severe one. In that month, however, the :ather was very cold, and ice between six and seven feet thick rmed in the harbour, during which of course no temperature servations of the sea could be taken. On March 4 and 5 the : broke up, and in the open space between the floating ice-ocks the temperature of the sea was found to be 29°·0. Of e Spitzbergen ice it is remarked that nothing had yet been ard of it, but that it could not be far off, as north-easterly inds had been blowing all February. Mr. Thorlacius observed ı aurora on January 24, with a triple arch and faint traces of a urth bow within the other three arches close down on the horizon, ing the first time an aurora of this description has been seen r him since he began his regular meteorological observations in 345.

THE *Monthly Weather Review* of the Dominion of Canada r February, 1885, presents some points of interest. At ictoria, British Columbia, the mean temperature was 9°·0 igher than the average, and 13°·8 higher than February last ear; but, on the other hand, to the east of the Rockies, tem-erature was under the average, the greatest defect from the verage, 13°·3, occurring at Port Stanley. At Toronto the ıean temperature was only 11°·1, being 11°·1 lower than the verage of forty-five years, and with the single exception of ebruary, 1875, when the mean fell to 10°·2, was the coldest ıonth recorded at the observatory during the past forty-five ears. Generally the month was remarkable for the cold which ırevailed nearly everywhere, and also for the very stormy weather vhich was experienced over the Lake Region, and in Eastern Canada, between the 8th and 11th. On the 9th tempera-ure fell in Manitoba to −48°·3 at St. Andrew's, and −46°·0 at Stony Mountain; and in Asiniboia to −47°·0 it Pheasant Forks. The proportion of sunshine re-:orded in each hour of the day during which the sun was above the horizon is given for twelve stations, giving a mean esult of 39 per cent. of actual as compared with possible hours of sunshine. It is remarkable that only at one of the twelve stations, viz. Cornwall, was 100 per cent. recorded during any day of the month. The number of predictions or forecasts of weather issued during the month was 523, of which 80 per cent. were fully, and 92 per cent. either fully or partially, verified. As regards the three storms which occurred, thirty-nine warnings were issued and cautionary signals at the various signal stations, each of which was verified in every particular as to the force of the wind; and with respect to the predictions as to the probable changes in the direction of the wind, 90 per cent. were fully and [illegible] per cent. were either fully or partially verified.

[illegible]RT E. PEEK sends us his First Report of a [illegible]ervatory established at Rousdon, Devon, in [illegible]The Report presents some of the features of [illegible]on during 1884. Fully half a quarto page is given to a somewhat popular account of the weather of each month. A few illustrations are given, of which the first shows by curves the mean monthly temperature of Greenwich for the forty years ending 1873, and the mean at Rousdon for the months of 1884. Nowhere, however, is there printed in figures a monthly mean either of the pressure or the temperature of the air, the author contenting himself only with the extreme pressures and temperatures of the months. Subsequent reports will, no doubt, make good these omissions, and will continue, it is hoped, the comparison of the weather forecasts of the Meteorological Office, with the weather actually experienced in this district of Eastern Devon.

THE veteran zoologists of Cuba, *Science* states—Prof. Felipe Poey, who is now nearly eighty-six years old, and Dr. Juan Gundlach, who has completed his seventy-fourth year—are still engaged industriously in studying the fauna of that tropical island. Dr. Gundlach has been publishing his contributions to the fauna of Porto Rico in the *Annals* of the Spanish Society of Natural History. The vertebrates (including fishes by Poey) have all appeared, and recently the freshwater marine mollusca have been issued. Gundlach has been publishing every month eight octavo pages in the *Annals* of the Havana Academy of Sciences—a contribution to the mammals, birds, and reptiles of Cuba—and is now at work upon the insects, of which the Lepidoptera are already nearly completed, and occupy already nearly 400 pages. Poey has published the fishes of the island in the *Annals* of the Spanish Society of Natural History, and Arango has discussed the mollusks. It is to be hoped that these still vigorous naturalists will live to see the completion of the work they have undertaken with so much zeal.

THE French Academy of Sciences has appointed a new commission on aërostats consisting of MM. Faye, Fremy, Jamin, Tresca, Cornu, and Perier.

THE French Society of Physics will meet as usual to-day, in the rooms of the Société d'Encouragement, to exhibit all the new apparatus invented during the year.

PROF. TYNDALL will begin a course of five lectures at the Royal Institution on Tuesday next (April 16) on "Natural Forces and Energies."

THE arrangements for the remaining April Popular Science Lectures at the Royal Victoria Hall, Waterloo Road, are as follow:—April 21, P. H. Carpenter, D.Sc., on Greenland. April 28, Dr. J. A. Fleming, "Our Nimble Servant, Electricity, and what we can make it do."

EXHIBITS in the Fish Culture Department of the forthcoming Inventions Exhibition are already being placed in the several spaces allotted to them. They include hatching-boxes showing the manner in which fish eggs are incubated; feeding-boxes in which the fry are inserted after losing their *umbilical sac*, and numerous appliances and apparatus necessary to carrying on the work of fish-culture successfully. There will also be shown various species of fish in different stages of development reared artificially, together with models of fish-farms, oyster-culture establishments, and a number of other exhibits of an interesting nature.

A COMMISSION appointed by the French Government to inspect the forests of Tunis, and to make proposals with regard to afforestation, has recently presented its report. In the districts south of the Medjerda valley the so-called forests are mere brushwood, composed of the callistus, juniper, Aleppo pines, and small oaks. The land is cleared for pasturage and cultivation, and only here and there are seen groups of larger trees, such as Alpine firs and olives Nothing is therefore to be gained by preserving here, and the cost would be very great;

but it is nevertheless recommended that some steps be taken to protect trees and shrubs which exercise a beneficial influence on the *régime des eaux*. The Kroumir mountains to the north are of a totally different character. Magnificent forests of old trees exist in them, which attain as great dimensions as those in the best French forests. They contain magnificent cork trees and white oaks (*Q. Mirbeckii*), with trunks three or four metres in circumference and ten to fifteen metres in height to the first branches. One forest covers 100,000 hectares, and contains also the alder, willow, wild cherry, beech, poplar, holly, bay, and the tamarisk. This and some neighbouring ones should, the report advises, be strictly preserved. The bark and wood of the oak and cork would repay the expense.

We have received Mr. Morris's Annual Report on the Public Gardens and Plantations of Jamaica, which, as usual, contains various matters of much general and local interest. We have already referred, in noticing a similar report from Queensland, to the immense economical importance of such institutions as this, and we are glad to perceive that such competent authorities as the late Royal Commissioners in the West Indies and Sir Joseph Hooker have publicly recognized the value of Mr. Morris's labours. The former suggest that in all the lesser islands "plant committees" of the residents should at once be formed to correspond with the establishment in Jamaica, while Sir Joseph Hooker, in commenting on this recommendation in his letter to the Colonial Office, stated that there can be no doubt that the future prosperity of the West Indies will be largely affected by the extension to other islands unprovided with any kind of botanical establishment of the kind of the operations so successfully carried out by Mr. Morris in Jamaica. But he thinks that mere committees will not be enough: botanical stations on a cheap basis are an essential condition for doing anything in an effective way. The money value of rain in Jamaica is well shown in a paragraph in the report quoted from Mr. Maxwell Hall's estimate. A comparison has been made between so many inches of rain per annum and so many casks of sugar per acre. Thus there were 1559 casks per acre for 79 inches rainfall and 1441 casks with 56 inches, so that the difference due to a larger or smaller island rainfall is on an average nearly one-tenth of the export sugar crop. This one-tenth export crop, for sugar and rum, represents in value nearly 100,000*l*. But if other produce, which is likewise affected by a greater or less rainfall, such as coffee and pimento, the difference would amount to a very considerable sum. During the year considerable attention was devoted in the herbarium to the medicinal plants of the island, and to forming not only a collection of botanical specimens, but also of the barks, roots, and the portions used for medicine. The value of this herbarium to the commercial interests of the West Indies was shown while working up the botanical classification of the indigenous plants capable of yielding fibre. It was found that the common native *Agave* (aloe) of Jamaica was not, as had been represented in books on Jamaica plants, the *Agave americana*, but an entirely different species, the *Agave heraite* of Salmdyck. The application of this difference, which appears to him only one of botanical nomenclature, to the industrial arts is that, under the belief that this plant was *Agave americana*, and therefore capable of yielding valuable fibre, large sums of money were spent and lost in getting out machinery to clean fibre which was of inferior quality.

At the end of the report on the Jamaica public gardens above referred to, Mr. Morris mentions some curious instances of superstitions among the negroes with regard to plants. The plantation labourers believe that if they take up the horse-plantain suckers (*i.e.* those with long fingers), and then take up one of the maiden plantains (with the short fingers) while the dew or juice is still fresh upon their cutlasses, and they cut the one plant the maiden plantains will produce horse-plantains, and the reverse. It is said by them to be a matter of common experience. It is believed also to be unlucky to point the finger when speaking of any growing plant in a provision ground, or even to name a plant which has recently been planted. It is stated even by intelligent Europeans that if the seed of the shaddock (*Citrus decumana*) is planted, there is but one in a whole orchard that will produce good and pleasant fruit, and also that the other fifty-two seeds in a shaddock, only two of which produce the real shaddock, while the others produce a variety of lime and lemon as the sweet lime, forbidden fruit, grape fruit, chadec fruit, and orange!

According to an article in the last number of the *Mittheilungen aus der ostasiatischen Monatszchrift für den Orient*, by Herr Friedrich Müller of Vienna, on the palæography of the Philippine Islands, the inhabitants of the archipelago of Malay descent possess a writing which is going more and more out of use and is being replaced by the Latin writing introduced with Christianity by the Spanish missionaries. The original writing, which is on the whole of the same form among the various tribes, such as the Tagalen, Ilocos, Visayas, Pampangas, is connected first with the writing of the people of the Celebes (Bugis, Macassars), and of Sumatra (Battak, Redschang, Lampang), and the forms point to India as the common origin of all. But whether the writing of the Malay peoples came direct from India, or through the intermediary of another writing; from which Indian alphabet it came, and to which province; and at what time,—are questions which have been competent scholars have answered in various ways, and which may therefore be regarded as still open. To those who desire to pursue the subject two interesting recent articles may be recommended. One, by Prof. Kern, of Leyden, appears in the well-known Dutch magazine, *Bijdragen tot de Taal, Land en Volkenkunde van Nederlandsch-Indië*, vol. iv. No. 10, 1880, which is a critical examination of the whole question. The other, in Spanish, by Señor Pardo de Tavera, is published as a pamphlet, and is entitled "A Contribution to the Study of the Ancient Alphabets of the Philippines." The special value of the latter is that it investigates the subject more thoroughly than any of its predecessors with special relation to the Philippines, and illustrates it by much that is original from the old literature of the archipelago. It is accompanied by plates, containing copies of no less than twelve Philippine alphabets. Nos. 11 and 12, however, appear to be identical, with the exception that they are produced with different instruments. No. 11 is probably written with a pen on paper, while No. 12 was probably cut by the knife into wood. Even with this deduction there are still eleven distinct alphabets in this archipelago alone.

The stone implements, shell heaps, and other prehistoric remains of Japan have already received some attention at the hands of Profs. Milne and Morse, and of Herr von Siebold, the Austrian *savant* in the diplomatic service in Tokio. Until quite recently, although the Japanese prized stone implements and the like, they appear to have done so on account of their peculiar shapes and as curiosities rather than because of their scientific importance. A Japanese gentleman filling a high official position has, however, just published a volume entitled "Researches on the Ancient Stone Implements of Japan," for a description of the contents of which we are indebted to the *Japan Mail*. The author, Kanda enjoys high reputation as an antiquarian. His book contains twenty-four plates, to each of which are appended numerous descriptions of the objects delineated, with their measurements and other details. The plates are not tinted, as they ought to be, in imitation of the colours of the originals, many of which are of a high order of beauty—serpentine, jade, jasper, amethyst, agate, calcedony, &c. They give the exact shapes and dimensions of all the stones in Kanda's collection. His object is not to ventilate his own opinions on [illegible]

tiquarians abroad with data for comparing the stone implements of Japan with those found elsewhere. In a short treatise of eight pages he describes the beliefs universally current in Japan on the subject of these remains. Dividing stone implements into "chipped" and "polished," he mentions four varieties of the former, which, translating the original Japanese names, he calls arrow-heads, spear-heads, rice-spoons of the mountain gnomes, and pound-stones—the last being really hoe-heads. The three first are known all over Japan, but become more and more numerous as one approaches the north. They are supposed to have been used by the Ainos. Of the "polished" stone implements there are six principal varieties, vulgarly known as thunder-bells, thunder clubs, stone daggers, dagger-heads, *magatama* and *kudakama*, or curve and tube-shaped jewels. The thunder-bells, so called, are evidently axe-heads; they are found everywhere, but chiefly in the north. The "thunder-clubs" are beautifully ornamented, while their shape and size—occasionally they are found as much as five feet long and five inches in diameter—suggest the idea that they served as insignia of authority rather than as weapons of war. The prehistoric pottery is Kamiaka pottery, from the name of the locality in Northern Japan where it was first discovered. Like the stone implements, it occurs with greater frequency the farther north we go. The general conclusion is thus suggested that the aborigines of Japan were gradually pushed northward by invaders from the south, but where the distinction is to be drawn between the races known as Tsuchigumo, Yezo, and Ainu is a question of future determination. No metal implements have ever been found with this pottery, whereas it is constantly associated with all the stone implements enumerated above. In the ancient tombs, which exist everywhere throughout Japan except in Yezo, there are unearthed several varieties of stone implements, and with them occur metal implements, together with a species of pottery known as *Gōgi* ware, after a priest of that name who came to Japan from Corea in the eighth century, and who is supposed to have introduced the potter's wheel. The name is doubtless improperly applied to the ware found in the ancient tombs, for in court relics now preserved and dating back to the eighth century there is ware incomparably superior to this so-called *Gōgi* ware, which should therefore probably be referred to a period much more remote. The stone implements found in these tombs are for the most part of an ornamental character, though some may have served for agricultural purposes. The former include the *magatama*, or "curved jewels" which were used as pendants. Some of them are of nephrite and chrysolite, minerals never yet found in Japan, so that these ornaments must have been brought over from the Asiatic continent. Mr. Kanda thinks that the ancestors of the present Japanese, when they arrived in Japan, brought with them from their old home metal implements which, not being sufficient for all, were appropriated by the privileged few, the majority of the people being thus driven back to stone implements. This curious theory would explain the circumstance that many of the thunder-clubs already mentioned are so beautifully ornamented as to indicate, almost with certainty, the use of metal chisels; but archæologists will probably prefer leaving this circumstance unexplained to adopting so violent an explanation.

We have received the *Proceedings* of the Windsor and Eton Scientific Society for 1884, with the Society's diary and the presidential addresses since its formation in 1881. One naturally looks in the *Proceedings* of this and similar societies to the local work—the papers with some of the *locus in quo* in them—rather than to the more general papers read and lectures delivered, and we find more than one instructive communication on the subject of the old Roman town of Silchester, near Reading; a paper on the trees of Windsor Forest, by Dr. Gee; whilst amongst the papers read during the four years, but not printed, we notice one on some bronze implements found in the Thames near Windsor, on carnivorous plants found in the same neighbourhood, and on recent explorations of a tumulus at Taplow. The Society, which does all its interesting work on a subscription of five shillings from each member, is affiliated with the Albert Institute of Windsor, and was formed in consequence of the success of an exhibition of microscopes and other scientific objects which formed one of the fortnightly entertainments provided by this institute.

THE additions to the Zoological Society's Gardens during the past week include a Rhesus Monkey (*Macacus rhesus* ♂) from India, presented by Mr. P. J. Edmonds; a Greater Sulphur-crested Cockatoo (*Cacatua galerita*) from Australia, deposited; two Great Kangaroos (*Macropus giganteus* ♂ ♀), eight Silky Flower-birds (*Ptilonorhynchus violaceus*) from New South Wales; two Red Kangaroos (*Macropus rufus* ♂ ♀) from Australia; two Bennett's Wallaby (*Halmaturus bennetti* ♂ ♀) from Tasmania; a Roan Kangaroo (*Macropus erubescens*), two —— Wombats (*Phascolomys* ——) from South Australia, received in exchange; two Sumatran Rhinoceros (*Rhinoceros sumatrensis* ♂ ♀); a Rufous-tailed Pheasant (*Euplocamus erythrophthalmus* ♀) from Malacca; a Bar-tailed Pheasant (*Phasianus reevesi* ♀) from North China; two Peacock Pheasants (*Polyplectron chinquis*) from British Burmah; a Silver Pheasant (*Euplocamus nycthemerus* ♀) from China, a Cuvier Heron (*Ardea cinerea*) from America, purchased; a Bonnet Monkey (*Macacus sinicus*), a Black Lemur (*Lemur macaco*), born in the Gardens.

OUR ASTRONOMICAL COLUMN.

ANCIENT OCCULTATIONS OF ALDEBARAN.—In NATURE, vol. xxxi. p. 182, reference was made to an occultation of Aldebaran which Bullialdus found recorded in a Greek manuscript, and which it had been supposed was observed at Athens on March 11, A.D. 509. The extract from the manuscript is given at p. 172 of the well-known work of Bullialdus, "Astronomia Philolaica." The observation is perhaps mentioned in somewhat undecided terms, inasmuch as it is rather implied that after twilight had ended the moon seemed to have occulted the star; nevertheless we have its position described as close to the moon at the time of observation; and further: "Stella quippe appendix erat parti, per quam bisecatur limbus Lunæ illuminatus." If we remember rightly, Strœt, amongst others, has pointed out that the occultation itself could not have been seen at Athens, but must have been observed at some more eastern station. The following are results of a recent computation in which the moon's place has been determined on the same elements which closely represent the occultations observed in China B.C. 62, February 14, and A.D. 361, March 20, relating to the planets Mars and Venus respectively, as well as other phenomena recorded previous to the fourth century.

A.D. 509, March 11, at 4h. 30m. Paris mean time

Moon's right ascension		4h 11m 23s	
,, declination		+12 55 40	
Hourly motion in R.A.		30 15	
,, ,, Decl.		+7 12	

The position of Aldebaran was in R.A. 4h 10m 16s, Decl. +12° 29′ 29″. The sidereal time at mean noon at Athens was 23h. 22m. 11s. Hence, calculating for Athens, we find the star disappeared at 3h. 7m., and re-appeared at 4h. 27m. local mean time; the sun set at 6h. 6m., or that the occultation occurred in broad daylight, and "post nonnas lucernæ" there would be a considerable distance between the moon and the star, as seen at Athens.

By way of testing the moon's place here employed, we may examine the circumstances of another occultation of Aldebaran, which Gaubil extracted from the Chinese historical works, and thus describes it:—"In the ninth year (period *Yuen-ming*), third moon, day *ping-chin*, the moon eclipsed Aldebaran;" this occurs in the records of the "Dynastie des *Tsi* du sud, la cour à Nanking." Gaubil gives the date March 29, A.D. 491. Proceeding as before we have for

A.D. 491, March 29, at 1h. 30m. Paris mean time

Moon's right ascension	...	...	4h 35m 53s
,, declination	...	...	+12° 53′ 1″
Hourly motion in R.A.	...	...	29′44″
,, in Decl.	...	...	+7′39″

The position of Aldebaran was in R.A. 47° 50′ 44″, Decl. +12° 10′ 15″. The sidereal time at mean noon at Nankin was 0h. 29m. 36s., and, calculating for that place, we find the star disappeared at 9h. 2m. local mean time, and would set at 9h. 14m., so that its altitude at disappearance was only 2°·3. Whence, assuming the accuracy of these computations, it is clear that the occultation could not have been seen as recorded at Nankin, if the moon's place about the epoch to which they refer were sensibly behind that deduced, so as to render possible an observation in twilight at Athens of the occultation of March 11, 509.

This result for the circumstances of disappearance of Aldebaran at Nankin in 491 reminds us of a similar observation made in London on the occultation of the same star, September 14, 1717, probably from the roof of the Royal Society's house in Crane Court, Fleet Street, whence, we are told, on the occasion of the total solar eclipse in 1715 there was a free horizon. "On the 14th of September, in the evening, for the first time the moon returned after a long interval to hide *Palilicium*; and the sky was extraordinarily clear at London, so that the moon and the star were seen to rise in the horizon at the same time; the immersion of *Palilicium* was at 9h. 6m. 20s., the moon not being 3′ high, in the very middle, as it were, of the eastern limb, over against the northern part of that small *macula* which Hevelius called *Stagnum Merridii*, and Ricciolus by his own name . . ."

BARNARD'S COMET.—A new computation of the orbit of this comet, by Mr. Egbert, of the Dudley Observatory, Albany, U.S., confirms that of Dr. Berberich, as regards the close approach which the comet makes to the orbit of Mars. At a true anomaly of 37° 35′, corresponding to heliocentric longitude 343° 52′ (equinox of 1884), the distance is within 0·008, the earth's mean distance from the sun being taken as unity, and a very close approach of the two bodies may have taken place, as before remarked, at the end of the year 1873. Dr. Berberich's period of revolution is 1958·9 days, that of Mr. Egbert 1970·3 days, an increase of only ten days on the latter period would suffice to have brought the comet and planet together in December 1873. The latest observation made by M. Perrotin, at Nice, in November, 1884, has not yet been brought to bear upon the direct calculation of the orbit, though Dr. Berberich's comparison of his elements therewith shows but small difference between calculation and observation. Barnard's comet does not quite attain to the orbit of Jupiter, the distance at aphelion being 0·555.

ASTRONOMICAL PHENOMENA FOR THE WEEK, 1885, APRIL 12-18

(FOR the reckoning of time the civil day, commencing at Greenwich mean midnight, counting the hours on to 24, is here employed.)

At Greenwich on April 12

Sun rises, 5h. 12m.; souths, 12h. 0m. 41·7s.; sets, 18h. 51m.; decl. on meridian, 8° 51′ N.; Sidereal Time at Sunset, 8h. 15m.

Moon (New on April 15) rises, 4h. 2m.; souths, 9h. 47m.; sets, 15h. 43m.; decl. on meridian, 3° 38′ S.

Planet	Rises h. m.	Souths h. m.	Sets h. m.	Decl. on meridian
Mercury	5 27	13 7	20 47	18 0 N.
Venus	5 10	11 41	18 12	5 26 N.
Mars	4 55	11 15	17 35	3 13 N.
Jupiter	13 13	20 30	3 47*	14 1 N.
Saturn	7 46	15 52	23 58	21 59 N.

* Indicates that the setting is that of the following day.

The Phenomena of Jupiter's Satellites are such as are visible at Greenwich.

April	h.		
14	6	...	Mars in conjunction with and 4′ south of the Moon.
14	20	...	Venus in conjunction with and 1° 6′ south of the Moon.
16	7	...	Mercury in conjunction with and 1° 2′ north of the Moon.
17	20	...	Mercury stationary.

GEOGRAPHICAL NOTES

THE Pescadores, which have recently been bombarded and occupied by Admiral Courbet, are a small group of islands lying in the Formosa Channel, about twenty-five miles off the west coast of Formosa. They are attached for administrative purposes to that island, and form one of the six districts into which it is divided. The islands are known to the Chinese as the Pang-hu-ting, or district of Panghu, and in Chinese geographical works more than thirty distinct islands are mentioned, but no distinction is made between the inhabited and uninhabited, large and small islands, nor between islands and mere rocks and reefs. The largest of the group is called Panghu, and from it the archipelago has doubtless derived its name. The main island is forty-eight miles in circumference, and the next in size, called Fisher's or West Island, is seventeen. According to the late Admiral Collinson, who surveyed it in 1845, the want of water, which the Chinese officers accounted for by the violence of the wind and the absence of sheltered valleys, give the island a barren appearance. Millet is extensively cultivated, and across its rows the ground-nut is planted. In sheltered spots sweet potato and a few vegetables are grown, but the inhabitants depend mainly on Formosa for vegetables and fruits. Pigs and poultry were abundant. The population of the two principal islands was stated then to be 5000, and of the whole of the islands 8000. The archipelago contains actually twenty-one inhabited islands, besides several rocks. They extend from 23° 13′ to 23° 48′ N. lat., and from 19° 16′ to 119° 37′ E. long. Their general appearance is flat, the summits of many of the islands being nearly level, and no part of the group being 200 feet above the sea-level. The two larger islands are situated near the centre of the archipelago, forming an extensive and excellent harbour between them. The capital of the whole is Makung or Macon—is situated on the north side of an inlet on the main island. The islands offer shelter in all states of the weather in the dangerous Formosa Channel. The archipelago was seized by the Dutch in 1622, and some remains of their fortifications are still to be seen; but in 1624 they left it for Formosa, where they remained till finally driven out by the Chinese pirate Koxinga.

PORT HAMILTON, the English Naval Station in the North Pacific, acquired during the past week, is the name correctly applied to the large Corean island of Quelpart, situated about sixty miles due south of the extreme point of the Corean peninsula, and situated between 33° and 34° N. lat. and 126° and 127° E. long. It has been described at great length by Hamel, the "secretary" of a Dutch vessel wrecked there on its way to Nagasaki in the seventeenth century. Hamel and his companions were kept captive in Corea for thirty-five years, when some of them succeeded in escaping. Hamel's story will be found in Pinkerton and other collections of voyages. During the present century it has also been visited occasionally in search of the crews of shipwrecked vessels. A glance at a map shows its position relatively to Japan, North China, Corea and the Sea of Japan, and its value as a naval station lower than any words could do. It is 150 miles distant from Nagasaki, about 100 miles from Nagasaki, and lies in the mouth of the exit to the south from the Sea of Japan. It is described by Mr. Griffis, a recent historian of Corea, as an oval, mountainous island covered with innumerable conical mountains. Open in many instances by extinct volcanic craters, the highest of which, being Mount Auckland, or Hanra, which is stated to be 6000 feet high. On the top are three extinct craters, one of which is a lake of pure water, and Coreans children are still taught to believe that the three fire-created men of the past still dwell on these lofty heights. The whole island is well cultivated; there are a number of towns, three of which are cities, but no good harbours. It has long been used as a place of banishment for criminals. The chief industry is the manufacture of straw hats, three from Quelpart being worn in Corea, which is a country of large [illegible]

from very ancient times, when it formed an independent ɔm. The origin of the great peak of Mount Auckland, renders the island so conspicuous, is thus given by the inɪts (we quote from Mr. Griffis): "Clouds and fogs covered a, and the earth trembled with a noise of thunder for seven and seven nights. Finally, the waves opened, and there ed a mountain more than 1000 feet high, and forty *ri* in ɪference. It had neither plants nor trees upon it, and s of smoke, widely spread out, covered its summit, which red to be composed chiefly of sulphur." The fullest recent nt which we possess is one published by a gentleman who l the place with the French Consul in Shanghai in 1851, to or the crew of a vessel, the *Narwhal*, believed to have wrecked there. The story of the visit was published at ime in an English journal printed in China. The inɪnts are Coreans of the ordinary type; iron appears to ɪd on the southern coast, and there were ample evidences ɪch comfort and even wealth among the islanders. Chrisy is said to have reached Quelpart through a Corean, who his way through North China to Hongkong, where he taught by the missionaries, and who then made his way to the island.

ɪE geographical subject proposed this year by the French lemy of Inscriptions for the Prix Bordin is "A Critical nination of the Geography of Strabo." According to the s laid down by the Academy, competitors are (1) to give ɪistory of the text of the work; (2) to characterise the lane of Strabo with reference to that of contemporary Greek ers, such as Diodorus Siculus and Dionysius of Halicarɪs; (3) to distinguish the information collected by direct rvation of places and that drawn by him from his predeɔrs; (4) to express definite conclusions on his critical method sing various documents. The papers should be in the hands be Secretary of the Institute not later than December 31, 5.

ɪHE Hungarian Society of Geography is engaged just now in ɪnising a Magyar expedition for the exploration of the regions ut the Urals, and principally of the Baskir country, where Uralo-Altaic peoples are disappearing. The Society regards s essential to study tribes which will soon be only a more or confused recollection. The exploration is to be anthropoical, ethnographical, and archæological.

ɪHE Director of the Museum of Ethnography in Paris has received from the Minister of Public Instruction a fragment the planking of the canoe in which MM. Crévaux, Bellet, l Ringel were ascending the river when they were murdered the Tejo-Picolmayo by the Tobas Indians. The Minister ɪt at the same time a collection of ethnographical water-colour ɪwings made by Ringel and annotated by Crévaux. These re recovered by M. Bueno, and sent to the French Legation Rio de Janeiro.

ɪN the *Bollettino* of the Italian Geographical Society for arch an attempt is made to determine the limits of the new Kingdom of the Congo," as recognised by the late Berlin ɔnference, and modified by the treaty concluded between the frican International Association, and Portugal on February 14. he territory as thus determined would be limited on the west r the Atlantic seaboard from Banana to Yabé (5° 45′ S. lat.), ɛn by the parallel of Yabé to the meridian of Ponta da Lenha; ɛn by this meridian northward to the Chiloango; then by the ft bank of this river to its source, and beyond that point by a ɪrved line to the Ntombo-Macata Falls on the Congo, leaving ɪ the French the station of Mboco, but reserving Mucumbi and fanianga; lastly, from the Ntombo-Macata Falls the Congo self to its confluence with the Bumba beyond the equator, here the boundary running north-west remains still to be deterɪined. The southern frontier follows the Congo from Banana ɔ a point a little above Nokki, the north bank remaining to the ɪssociation, the south to Portugal; then from near Nokki the arallel of this place as far as the river Kwango; then his river to about 9° S. lat., and thence a diagonal ine across the continent to Lake Bangweolo. Eastwards the oundary coincides with the west coasts of Lakes Bangweolo, anganyika, Muta Nzighé, and Albert Nyanza. On the north he frontier will follow the line of water-parting to be herebe determined between the Congo, Nile, Shari, and (Niger) river basins. Within these limits the new ɔ will have an approximate area of about 1,000,000 square miles and a population of probably 40,000,000, mostly of Bantu speech and Negro or Negroid stock.

THE same number of the *Bollettino* publishes a letter from Count Giacomo di Brazza, dated Brazzaville, October 22, 1884, in which the writer complains that his efforts to complete the triangulation of Stanley Pool were frustrated by the officer of the African Association, a certain Captain S., in charge of the left bank of the pool. To complete the work it was necessary to cross over to that side of the Congo; but the permission to do so was refused by the official in consequence of instructions issued by Colonel de Winton, "that all were to remain on their own side."

ON THE SALINITY OF THE WATER IN THE FIRTH OF FORTH[1]

IT is the purpose of this paper to state the methods employed for examining the salinity and alkalinity of estuary water at the Scottish Marine Station at Granton, and to describe and record six months' observations of the water of the River and Firth of Forth up to December 31, 1884.

(1) *Collection of Water Samples.*—To collect a sample of surface-water from a small boat it is sufficient to wash out the bottle with the water, and then hold it a few inches under the surface until it fills. The temperature of the water is taken by means of an ordinary thermometer in a copper case. On board a larger vessel the same thing may be done, the bottle being attached to a sounding-line and lowered over the side, or, without stopping the vessel, by means of a clean bucket, care being taken to draw the sample forward of the ejection-pipe of the condenser. When brought on board a thermometer is immersed for a minute, and the temperature noted. The water is then bottled, tied down, and labelled.

The water-bottle employed for obtaining samples from any depth beneath the surface consists of a brass basal disk supporting three radiating sheets of brass surmounted by a brass dome, on the top of which there is a ring for the line. The basal plate has an india-rubber ring fixed upon it, and its under surface has two rings for attaching the lead, and a stopcock for running off the water. There is also a brass cylinder, the edge of which rests upon the india-rubber ring when the instrument is closed.

On board the *Medusa*, the steam-yacht of the Marine Station, the water-bottle is attached to the sounding-line, which is wound on a drum worked by a small deck-engine. It has a 7-lb. lead attached to it, the stopcock is closed and a little plug screwed in to prevent the entrance of mud should it strike the bottom. It is then lowered, the slip-cylinder being held in the hand. When the desired depth is reached the slip is let go; it crashes down on the frame and is guided by the brass strips on to the india-rubber ring, on which it presses, and so firmly incloses a sample of water. It has been found necessary to let down one or two cylindrical weights, slipping on the line, after the slip has struck the body, in order to press it firmly down. Repeated trial and continuous use have shown this manner of water-collecting to be satisfactory.

The bottles used for preserving the samples are glass-stoppered, blue glass half-Winchesters, which hold about 1·5 litres. They are packed in boxes, fifteen in each, so as to be carried easily and safely. Each bottle is labelled as it is put aside, with particulars of the date, hour, and temperature.

The temperature below the surface is ascertained by means of the Negretti and Zambra thermometer in the Scottish frame, which was described to this Society in July, 1884 (*Proceedings*, vol. xii. p. 927).

When each sample of water is taken, the following observations are made and recorded:—Date; hour; position by bearings; depth of water;[2] depth from which sample was taken; temperature of the water at that depth; temperature of the air; nature of the weather, wind, and state of sea; state of tide; colour and transparency of the water.[2]

The colour of the water is observed by sinking a disk of iron, painted white, to the depth of a few feet or fathoms, according to circumstances, and noting its colour. The transparency may be very roughly measured by observing the distance to which the disk remains visible.

It is important that the actual notes of all observations be

[1] Abstract of a paper read at the meeting of the Royal Society of Edinburgh, January 5, 1885, by Hugh Robert Mill, B.Sc., F.C.S., Chemist to the Scottish Marine Station, Granton, Edinburgh.

[2] These are sometimes omitted in the case of surface samples.

preserved for future reference should uncertainty arise regarding them. There are difficulties in doing this, for it is not easy on a small vessel, when there is any sea on, to keep an ordinary note-book from getting wet. It is most convenient to use cards with memoranda of the observations to be made printed on them, which are kept in a small leather case, and when each card is used, it may be slipped beneath the others, as is done in a date-case. The cards can be conveniently kept in boxes, and may be readily and rapidly referred to at any time.

Determination of the density.—The density of the samples of water collected in the Firth is determined by means of a very delicate hydrometer of the form used on board the *Challenger*. The hydrometer is made of glass, the tubes for body and stem having been very carefully selected to ensure uniformity of diameter. The instrument has a body of about 5 cm. diameter and 12 cm. long; the stem is nearly the same length, and has a diameter of 3 mm. The process of making and calibrating the hydrometer has been described in great detail by Mr. Buchanan in his *Challenger* report on the specific gravity of ocean water ("*Challenger* Rep. Phys. Chem.," vol. i. pt. ii. pp. 1-4.)

The hydrometer which has been used at the Marine Station is provided with seven movable weights, which can be attached to the top of the instrument, and so increase the weight of the hydrometer from 150·1478 grms. to 155·8390 grms., through thirty six gradations. The volume of the bulb and stem of the instrument is 150·2070 cc. at 0°·4, and its cubic contents is known; the volume of the 100 mm. area stem is divided is 0·83 cc., and as it is assumed to be uniform the volume of each millimetre of the stem is taken as 0·0083 cc.

The density of each water-sample was taken [illegible] using a weight that did not immerse more than the top of the stem, then adding another to immerse it [illegible] A table giving the volume of the hydrometer at every [illegible] a degree Centigrade from 0° to 25° has been drawn up; this table the volume of the body at the observed [illegible] taken; the volume of the stem immersed is got from another table, which gives the value for each half millimetre and 100. These added together give the total immersed volume, and the weight being taken from another table gives this volume, gives the density *at the observed temperature*. A mean of the two densities is taken, and reduced from the means of the two corrected observed temperatures to 17·5° C. (*Challenger* Rep. Phys. Chem., vol. i. pt. ii. pp. 1-4, part 1, p. 70).

Advantage was taken of the double determination of density and of a number of separate experiments to form an idea of the probable error of an individual determination. The result showed that the probable uncertainty is not more than

Map of part of the River and of the Firth of Forth. (20-fathom line; ——.)
Stations for water samples—I. Alloa; II. Kincardine; III. Hen and Chickens Buoy (near Grangemouth); IV. [illegible]; V. Owne Bassens (near Inchcolm); VI. Harvet Buoy (near Inchkeith); VII., IX., X., XI. See also [illegible]
May; S, Scottish Marine Station.

0·00005, taking pure water as 1·00000, and that consequently, in considering the relative densities of the water in the Firth, the fourth decimal place is certain.

The amount of total halogen was determined by Mohr's volumetric method, but, as the probable error was so great as to render the second decimal place in the per milleage uncertain, no reliance can be placed on the results. The largeness of the uncertainty is due, in part at least, to the disadvantageous position in which the determinations were made—a floating laboratory where the atmosphere was always more or less laden with saline particles.

The alkalinity was determined by Tornoe's method with standard solutions of hydrochloric acid and of potash.

The quantity represented by an alkalinity is very small, although the number used to express it is large. An alkalinity of 50 means that in a litre—say 1026 grammes—there is 0·05 gramme of carbonic acid as calcium carbonate; that is, a percentage of 0·00487, which, from the inaccuracy of the determinations, might vary from 0·00398 to 0·00476.

Notes of Previous Work on Estuary Water

In 1816 Dr. John Murray read a paper to this Society on the composition of sea-water, the samples which he analysed being taken from the Firth of Forth near Leith. The paper (*Trans.* R.S.E. for 1816) contains results of great theoretical value, which were instrumental in modifying the views [illegible] ence of salts of different bases and acids in solution, and altogether changed the mode of analysis of sea and [illegible] waters. Attention was given more particularly to the [illegible] constituents, and no observations seem to have been made by Dr. Murray on the variations in salinity at different parts of the Firth.

Dr. John Davy published a paper (*Edin. New Phil. Journ.* xxxvi. p. 13 in 1843, on "The Temperature and Specific Gravity of the Water of the Firth of Forth." He examined the temperature and density of the water at the end of [illegible] on eight occasions at intervals of about a month. [illegible] Davy's intention to continue the monthly observations for a number of years, but, as he had to leave Edinburgh, [illegible] stopped. Since no particulars as to how the [illegible] determined were given, it is impossible to compare [illegible] others observed at a later date.

Dr. Stevenson Macadam investigated the [illegible] of the Clyde in 1855 (Brit. Assoc. *Reports*, 1856, p. [illegible]) observed the specific gravity at more than [illegible] determined the total solids and chlorine in each. [illegible] investigations he examined the Plains of Cloomond [illegible] The results are recorded in the *Proceedings* of the Society for 1866 (*Proc. Roy. Soc. Ed.*, p. 8).

Prof. Kyle, of Dublin, [illegible]

on the River Plate, in the same way as Dr. Mac-on the Clyde. Mr. F. Newman has kindly supplied slation of Kyle's Spanish pamphlet ("Algunos Datos la Composicion de las Aguas del Rio de la Plata"), chart of the Plate, with the water-sampling stations. The brought out by Prof. Kyle are interesting, but, like the observers cited above, he neglects to mention whether ecific gravities are reduced to 0°, to 4°, or to 15°·56, or r water at 0°, 4°, or 15°·56 was taken as unity. It is re impossible to consider the results except as purely e to the estuary in question, and no comparison between ferent investigators can be made.

Cattegat, Skagerrack, Baltic, and north-eastern parts North Sea have been made the subject of very careful and ged examination by various Danish and German scientific rs. Water-samples have been taken regularly for a num-years at various points along the coast, and from light-and light-ships at considerable distances from land. The of the examination of these samples from 1872 to 1881 ulated in connection with the meteorological conditions, ally with respect to rainfall, in a recently issued paper by ommission in Kiel for the scientific investigation of the n seas.[1] The general low densities of these waters and the ons to which they are subject, make the conditions which there not unlike those in an estuary.

le it is fully realised that it will take years of consecutive ations to thoroughly settle the relations of the fresh and ter in an estuary, and that many conditions, such as the , law of the tides, and rainfall over the area drained by ain-pal rivers and its tributaries must be taken into ; it is considered expedient to state the results observed ix months, from June to December, 1884, on the Firth rth. These results are purely preliminary; but as little on has been given such matters hitherto, they may prove rest, and may lead to suggestions for improvements in g on the work.

Firth of Forth.—The River Forth rises in the valley n Ben Lomond and Ben Venue, is joined near Stirling by rth, and gradually merges into the Firth of Forth, the ion is to view the river as ending at Queensferry, but for con-e the term "Firth of Forth" may be applied as describing ree and Firth proper from Alloa to the Isle of May, a c of *fifty-five* miles. According to Keith Johnstone the ained by the Forth is 500 square miles. Few large rivers to the Firth. Those of any importance are: on the north e *Black Devon*, at Clackmannan; and the *Leven*, at Leven: south side there are the *Carron*, at Grangemouth; the a few miles further east; the *Almond*, at Cramond; the *of Leith*, at Leith; the *Esk*, at Musselburgh; and the near Dunbar.

n Alloa to within three miles of Queensferry the depth water is under 10 fathoms; there it increases, at first dly, then at the Banner Beacon abruptly, to over 30 fathoms, ue to Inchgarvie, to over 40 fathoms. This is the deepest the Firth, and the narrowest. The Forth Bridge is in of construction at this point. A very strong tide runs channels on each side of Inchgarvie, and the deep water is d to a very small area. The 10-fathom stream runs the northern shore, until off Kirkcaldy, where it widens a funnel shape, and approaches the shore on each side, s a short tract over 10 fathoms to the south of Inchkeith, as the *Narrow Deep*. Several small depressions of more fathoms occur between Queensferry and Inchkeith, and to the east of that island the 20-fathom area begins as a stream trending northward, and spreading out off Largo. e of May is connected to the mainland of Fife by a sub-plateau rising to less than 20 fathoms from the surface; ost four miles east of the May, depths beyond 30 fathoms nce.

e drawn from Aberlady Bay to Largo divides the Firth o very different halves. To the west of it the slope of is extremely gradual, and the depth slight; to the east shore slopes down abruptly, and the bed of the Firth is, ne or two insignificant exceptions, uniformly over 20 10 depths.

[1] *Jahr-Bericht—für die Jahre 1877 bis 1881.* Berlin, 1883: "Period-Beobachtungen der Salzgehalte im Oberflächenwasser in der Ostsee

Observations on the Surface Salinity in the Firth.—It is assumed that the amount of total salts may be deduced from the density, as if estuary water were ocean water diluted with pure water. This cannot be exactly the case, as the salts carried down by rivers are in quite different proportion to those found in the sea, and before the processes occurring there have had time to produce uniformity of composition—that is, where river-water predominates—the proportion of salts among themselves must vary. Consequently, until exact experiments can be made on this point, the interpretation of estuary densities by ocean-water tables must be taken with reservation, and it is better to view the densities as such, without reducing them to amounts of total salts. To get a preliminary view of the rate of freshening, it was determined in September 1884 to make a monthly trip for collecting water samples from the entire Firth; and on September 18 the *Medusa* proceeded from Inchkeith to Grangemouth for that purpose. Surface samples were taken every five miles, and bottom samples at each alternate station. Observations were made both in going and in returning. The intention to make the complete tour of the Firth in one day had to be relinquished, and the Inchkeith to May section was completed on the 29th. This double trip showed that the densities of the water samples decreased steadily, gradually, and uniformly from the May to Inchkeith, but that the change then became more rapid, the curve resembling a portion of a rectangular hyperbola. The second water sampling trip was on October 7 and 8; the water, beautifully clear and transparent, and of a deep green-blue colour at the May, became light green and less transparent about Inchkeith, and from Inchgarvie onwards it was yellow and very muddy. The results were similar to those of September. The November trip took place on the 10th and 11th; the weather was fine, almost summer-like, and, in consequence of previous heavy rains, all the rivers were in flood. The effect was a marked lowering of the density of the surface water, greatest in the upper reaches of the Firth, but quite perceptible at the Isle of May, which is almost in the open sea. The effect of this "spate" was to reduce the density at Inchgarvie from its mean of 1·02358 to 1·02029; that at the Oscar Beacon from the mean of 1·02438 to 1·02022; that at Inchkeith from 1·02472 to 1·02403; and those at Stations VIII. and IX. from 1·02505 and 1·02518 to 1·02458 and 1·02508 respectively. The December trip did not take place till the 25th, when my friend Mr. Ritchie was good enough to take charge of the eastern excursion. The day was fine, with a north-easterly breeze and a slight swell. On the 27th the yacht started for Alloa, but the morning, which was hazy, gave place to a day of fog, and it was impossible to proceed beyond Inchgarvie. The 29th and 30th were also misty, and this portion of the trip had very reluctantly to be dispensed with.

The effect of the tide obscures the changes of salinity in a certain extent in these monthly cruises, but, although the data are so few, they are sufficient to show that between Inchkeith and the Isle of May—that is, in the wide and open part of the Firth—the tidal effect is relatively slight and the variations in density very gradual, though perceptible; while from Inchkeith to Alloa the tidal effect increases with every mile, and the rate of change becomes more and more rapid. The following tables (I. and II.) give the figures observed in these consecutive trips:—

The mean of the Salinity, 82·5, at the stations going and returning is given here.

The maximum, minimum, and mean of all the density observations at each station, together with the number of cases which give the mean, are tabulated (Table III.). The temperature observations made on the monthly trips have not been alluded to here; they are intended to form a separate paper.

Note.—All the densities given are at 15°·56 C.

The change of temperature produces a corresponding change of the density of the water *en masse*, which has important bearings on convection currents, and which must also influence the rate of mixture of sea and river water, especially as the temperature of the river water is in winter usually below that of its maximum density.

An examination of Table III. shows that for maximum and minimum, as well as for mean observed densities, the increase is perfectly continuous until the last station is reached, when the maximum density is only probably greater than that at Station XI., the minimum is certainly less than that at Station VIII., and the mean is less than that at Station IX. It is not easy to find an explanation of this fact, for there is no river nearer than the Tyne at Dunbar, and there are no springs on the Isle of May, the lighthouse keeper being compelled to get all his fresh water carried from Crail. The proximity of the Firth of Tay may possibly account for the observation.

The difference between the density of the surface-water at high and at low tide is by far the greatest in the upper reaches of the Firth, and decreases more and more gradually. Beyond Inchkeith the difference is little noticed, in fact the water is found to be sometimes denser at a lower state of tide. This effect may be due to currents which are not taken account of in this preliminary investigation. The rate of change of density with the tide decreases very rapidly at first. At Kincardine the difference between high and low water is 1 in the second place of decimals, or, calling the density of pure water 10,000, it is 100; at Inchgarvie it is about 15, at Inchkeith 4, and beyond Inchkeith about 1; that is 1 in the fourth decimal place by ordinary notation.

The density of the surface-water was determined almost daily from August to December at the Scottish Marine Station, Granton, but the results were so variable, that dependence cannot be placed upon them as representative of the water in the Firth at that point. The density was always found to be greater at low water, and after some trouble the cause was ascertained. From the station westward for a distance of a mile and a half the shore dries at low water for from quarter to half a mile, and Cramond Island becomes a peninsula, on the west or further side of which the River Almond discharges itself. At high water there is from half to one fathom of water between Cramond Island and the coast, and the river, taking the shorter course, is carried by the ebb tide along the shore, and so reduces the density of the water in the neighbourhood.

As there was considerable time lost in devising and testing a suitable means of collecting samples of bottom water, the number of reliable cases for consideration is small.

It may be generally stated that the part of the Firth east of Inchkeith is the region where the difference between the density of surface and bottom water is least, and that the difference decreases steadily towards the May. Towards Alloa, on the other hand, the differences in the density between surface and bottom water are great, but they are greatly influenced by the tide. Table IV. gives details of nineteen comparisons between bottom and surface water.

At the Hen and Chickens Buoy, near Grangemouth, the depth is only 5½ fathoms, but the salinity is very much greater at the bottom than at the surface. The difference is least several hours before low water, but as the flood tide sets in, it appears to increase, and then to fall off again as the ebb commences. The only divergence from this rule noticed was on November 11, when the rivers were all much flooded and the current very rapid. It would appear that these observations confirm the theory that sea water ascends rivers along the bottom under the influence of the current of fresh water.

TABLE IV.—*Bottom Water at Hen and Chickens, near Grangemouth* (III.)

roughout this paper the density of the water is given as ed to 15°·56 C. (60° F.). It is *specific gravity* at 15°·56 ed to pure water at 4° C. as unity.

e water-sampling stations and the principal contour lines of are shown in the chart of the Firth of Forth (Fig. 1).

THE PEARL FISHERIES OF TAHITI

RECENT issue of the *Journal Officiel* contains a lengthy report by M. Bouchon-Brandely, Secretary of the College rance, who was sent by the Ministry of Marine and the nies on a mission to Tahiti to study questions relating to r-culture there. The principal product of what M. dely, with "the summer Isles of Eden" fresh in his mind, "*notre belle et si poétique colonie de Tahiti*," is mother-of-

All its trade is due solely to this article, which for a ry has regularly attracted vessels to the islands which com- the archipelagoes of Tuamotu, Gambier, and Tubuai. mother of-pearl which is employed in industry, and espe- in French industry, is furnished by various kinds of shells, ost estimated, variegated, and beautiful of which are those e pearl oyster. There are two kinds of pearl oysters—known under the name of pintadine (*Meleagrina margarit-*, is found in China, India, the Red Sea, the Comoro ls, North-Eastern Australia, the Gulf of Mexico, and ially in the Tuamotu and Gambier archipelagoes; the , more commonly called the pearl oyster (*Meleagrina radi-* comes from India, the China seas, the Antilles, the Red and Northern Australia. The shell of the former is harder, tinted, more transparent, and reaches greater dimensions the latter. Some have been found which have measured centimetres in diameter and weighed more than ten kilo- mes, while the *Meleagrina radiata* rarely exceeds ten centi- s at the most, and never weighs as much as 150 grammes. varieties supply pearls, those of one kind being at one more favoured, at another time those of the other. This ds on fashion; but, on the whole, those found in the great line are more beautiful, and the colour more transparent, those of its congener. The amount of the trade from Tahiti rls cannot be stated with accuracy, as there is much clan- e traffic, but M. Brandely puts it down approximately at oo francs, England, Germany, and the United States being hief markets for the fine pearls. The great pintadine is n great abundance in the Tuamotu and Gambier islands. ituation there is very favourable to them; in the clear and l waters of the lagoons they have full freedom for deve- ent, and are undisturbed by storms. Mother-of-pearl is in almost every one of the eighty islands which form the pelagoes Tuamotu and Gambier. These belong to France, g been annexed at the same time as Tahiti and Moorea, ave a population of about 5000 people, all belonging to laori race. M. Brandely gives an interesting description se little-known islands and people. The latter appear to always on the brink of starvation, as the islands, which are sed mainly of coral-sand, produce hardly anything of a vege- nature. While the neighbouring Society islanders have every- without labour and in abundance, the unfortunate inhabitant amotu is forced to support existence with cocoa-nuts, almost ly fruit-trees which will grow on the sandy beach, with d shell-fish which are poisonous for several months of the and often they have to kill their dogs for want of other l food. There are no birds, except the usual sea-birds; ahrepels, except those brought by man; no food resources ary to European life, except what is brought by ships. gh the people are gentle and hospitable, they practise alism, and M. Brandely suggests that it is pitiless hunger which has driven them into this horrible custom. These ble people are the chief pearl-divers of the Pacific; in- it is their only industry, and women and even children part in it. There is at Anaa, says the writer, a woman who o down twenty-five fathoms, and remain under water for minutes. Nor was she an exception. The dangers of ork are great, for the depths of the lagoons are infested by , against which the divers, being unable to escape, are to wage battle, in which life is the stake. No year without some disaster from sharks, and when one n all the divers are seized with terror, and the fishing is ed for a time. But gradually the imperious wants of life them back to the sea again, for mother-of-pearl is the cur- oin of the Tuamotu. With it he buys the rags which cover him, the little bread and flour which complete his food, and alcohol, "that fatal present of civilisation," for which he exhibits a pronounced passion. Twenty or thirty years ago the trade in mother-of-pearl in the Tuamotu archipelago was very profitable for those engaged in it. For a valueless piece of cloth, a few handfuls of flour, or some rum, the trader got half a ton of mother-of-pearl worth one or two thousand francs, or even fine pearls of which the natives did not know the value. The archipelagoes were frequented by vessels of all nationalities; mother-of-pearl was abundant, and pearls were less rare than they are now. The number of trading-ships increased; there was competition amongst them, and consequently a higher price to the natives, who fished to meet the new demand with improvident ardour. The consequence is that the lagoons are less productive, and that even the most fertile give manifest signs of exhaustion. The prospect of having the inhabitants of Tuamotu thrown on its hands in a state of helpless destitution, as well as of the disappearance of the principal article of the trade of Tahiti, and an important source of revenue to the colony, alarmed the Colonial administration, and the Ministry of Marine and the Colonies in Paris. Accordingly, M. Brandely was selected to study the whole subject on the spot. The points to which he was instructed to direct especial attention were these: (1) The actual state of the lagoons which produce oysters; are they beginning to be impoverished, and if so what is the cause, and what the remedy? (2) Would it be possible to create at Tuamotu, Gambier, Tahiti, and Moorea, for the cultivation of mother-of-pearl, an industry analogous to that existing in France for edible oysters? Would it be possible by this means to supply the natives of Tuamotu with continuous, fixed, remunerative labour which would render them independent, and remove them from the shameless cupidity of the traders? Could they not be spared the hardships and dangers resulting from the continued practice of diving, and be turned to more fixed sedentary modes of life, by which they might be raised gradually in the social scale? (3) Should the pearl fishing in the archipelagoes be regulated, and, if so, what should be the bases of such regulations? It was on the mixed economical and philanthropic mission here indicated that M. Brandely went to Tahiti in February last. The statistics did not show any decline in the production of mother-of-pearl, but a careful study on the spot showed that this was due to the great amount of the clandestine traffic, and that the lagoons were growing less productive day by day, that beautiful mother-of-pearl was becoming rarer, and in order now a-days to get oysters of a marketable size, the divers are forced to go to ever greater depths. M. Brandely recommends prompt and vigorous measures be taken at once, as the lagoons of Tuamotu will soon be ruined for ever. The partial steps already adopted have been useless. The total prohibition of fishing in some of the islands for several years has failed, because it has been found that the pintadine is hermaphrodite, and not, as formerly was believed, unisexual. The cause of the impoverishment of the lagoons is excessive fishing, and nothing else. He thinks that it is possible to create in Tuamotu, Gambier, Tahiti, and Moorea a rational and methodical cultivation of mother-of-pearl oysters, analogous to that existing with regard to edible oysters on the French coasts, and to constitute for the profit of the colony an industrial monopoly which no other country can dispute, for nowhere else can such favourable conditions be met with.

SOCIETIES AND ACADEMIES

LONDON

Royal Society, March 26.—"On the Peculiar Behaviour of Glow Lamps when raised to High Incandescence." By W. H. Preece, F.R.S.

The experiments described had for their object the investigation of a phenomenon observed by Mr. Edison, who brought it to the author's notice last autumn. Between the limbs of an incandescent filament of a glow-lamp a thin, narrow platinum plate being fixed with an independent wire connection, and a sensitive galvanometer being placed in circuit between the filament and the platinum, a derived current is observed to pass through the galvanometer and through the rarefied space at the bottom of the limb when the main current is increased to a certain strength and the filament reaches a certain degree of incandescence, the strength of the derived current increasing with the increased brilliancy of the glowing filament. In the author's investigations Mr. Edison had made other lamps, in

which the centre conducting plate was of copper, iron, and carbon respectively; but the general effects were practically the same as when platinum was used. The currents (from Faure-Sellon-Volckmar cells) were increased gradually, the effects of each increase being carefully noted. The nature and resistance of the rarified space in the shunt-circuit had to be ascertained. Certain increments in the current were followed by a diffused blue effect in the globe, more or less intense, accompanied in such instance by a marked fall in the resistance of the shunt—pointing to an intimate connection between the two phenomena. The strength of the shunt-current when the faint blue tinge appeared was: with carbon, 3·42; with iron, 3·85; and with copper, 3·80 milliampères. No perceptible difference in the results was observable with lamps in which the centre plate was a fine wire or a very broad surface, nor when the plates were doubled. That the effect was due primarily to the "Crookes's bombardment," or the projection of molecules in right lines from the carbon filament on to the metal plate was confirmed by the following experiments:—Lamps were constructed varying the position of the plate. In one the plate was fixed at the end of a tube having a portion of the filament exposed to the plate; in this case, with an E.M.F. of 108 volts in the main circuit, the blue effect entered the tube. In another lamp the tube was so constructed that no portion of the filament was opposed by right lines to the metal plate; with 112 volts the blue in the globe became very marked; with 120 volts the bulb was hot, the tube cool. Another lamp was constructed with three branches at right angles to each other, and each metal plate taken in succession; no result was obtained, no current being evident in either section. All the experiments went to show that, when once the blue effect appeared, destruction was only a question of time. Hence this blue effect is an indication of the advent of disintegration, and a very useful warning of danger ahead. Whenever the incandescence of the filament is raised beyond a certain limit, the interior of the glass envelope is blackened by a layer of carbon which has been deposited by a Crookes's bombardment effect.

It was evident from the observations that the Edison effect is due to the formation of an arc between the carbon filament and the metal plate fixed in the vacuous bulb, and that this arc is due to the projection of the carbon particle in right lines across the vacuous space. Its presence is detrimental to the life of the lamp, and as its appearance is contemporaneous with the blue effect, the latter is a warning of the approach of a critical point and a sure indication that the E.M.F. is dangerously high. It is also clear that, as the Edison effect is only evident when we are "among the breakers," it is not available for practically regulating the conditions of electric light currents as its ingenious discoverer originally proposed.

Mathematical Society, April 2.—J. W. L. Glaisher, F.R.S., President, in the chair.—Dr. R. Stawell Ball, F.R.S., Astronomer Royal, Ireland, and Baboo Basu, of Bhowanipore, were elected Members.—The following communications were made:—New relations between bipartite functions and determinants, with a proof of Cayley's theorem in matrices, by Dr. T. Muir.—On eliminants, and associated roots, by E. B. Elliott.—On five properties of certain solutions of a differential equation of the second order, by Dr. Routh, F.R.S.—On the arguments of points on a surface, by R. A. Roberts.—On congruences of the third order and class, by Dr. Hirst, F.R.S.

Geological Society, March 11.—Prof. T. G. Bonney, D.Sc., LL.D., F.R.S., President, in the chair.—William Lester and Thomas Stewart were elected Fellows of the Society.—The following communications were read:—The granitic and schistose rocks of Donegal and some other parts of Ireland, by C. Calloway, D.Sc., F.G.S. The author first recalled attention to the current theories on the nature of the Donegal granitic rock, one which described it as a highly metamorphosed portion of a sedimentary series, another which regarded it as a mass of Laurentian gneiss. In his view, however, it was a true igneous granite, posterior in age to the associated schists. In six districts examined it was intrusive and sent out veins. The apparent interstratification with bedded rocks was explained as a series of comparatively regular intrusions. Where the granite was seen in contact with limestone, the latter contained garnets and other accessory minerals. No gradation could be discovered between the granite and any other rock, the junctions (even in the case of small fragments of schist immersed in granite) being well marked. The granite was distinctly foliated. In some localities there was merely a linear arrangement of the [illegible] the western margin of the granite [illegible] striping of light and dark bands, the colour of the [illegible] due to the abundance of black mica. The gneissic [illegible] attributed to lateral pressure, the existence of [illegible] associated strata was seen in the contortion of [illegible] rocks, in the production of cleavage in beds of [illegible] in the crushed condition of some masses, in the [illegible] folds, and in the production of planes of thrust. [illegible] of the pressure was perpendicular to the plane of [illegible] the granite. The schistose rocks of the region were [illegible] two groups. The *Lough Foyle* series consisted of [illegible] quartzose grits with a micaceous matrix, alternating [illegible] fine-grained satiny schists, black phyllites, and impure [illegible] stones and dolomites. The semicrystalline condition of [illegible] these rocks was characteristic. This series was well seen [illegible] derry and on Lough Foyle, and formed a broad belt [illegible] the south-west. These rocks were compared with [illegible] the Hill of Howth (north of Dublin, near Ingleton [illegible] low), and south of Wexford. The Leinster [illegible] masses were quite unlike the Wicklow Cambrians [illegible] strong resemblance to the slaty series of Anglesey. [illegible] lithologically intermediate between the Donegal and [illegible] groups, and from a comparison of all these areas he [illegible] ferred the Lough Foyle series, with some reservation, [illegible] Pelsidian system. The prolongation of the Lough Foyle [illegible] into the Grampian region was well known, and [illegible] served to connect some parts of the Scottish highlands [illegible] South Britain. The author was not prepared to [illegible] Donegal series with any American group, but the [illegible] affinities were rather with the Taconian than with the [illegible] The *Kilmacrenan series*, in which the granite is [illegible] described as crystalline, and older than the Lough Foyle [illegible] It was mainly made up of micaceous, quartzose, [illegible] and hydromagnesian schists, quartzites, and crystalline [illegible] stones. There were no indications in these rocks of a [illegible] morphism progressive in the direction of the granite. [illegible] was lithologically similar to the Montalbon series. [illegible] microscopic slides of Donegal and Leinster were [illegible] examined by Prof. Bonney, whose observations [illegible] of the author both as regards the nature and relations of [illegible] granite and the general characters and state of [illegible] the two schistose groups.—On hollow spherules of [illegible] occurrence in ancient British lavas, by Groville A. J. [illegible] F.G.S.

EDINBURGH

Royal Society, March 2.—Robert Grey, Vice-President, in the chair.—At the request of the Society's Council, Dr. Geikie, Director-General of the Geological Survey, gave an address on the recent progress of the Survey. He pointed out what would be the future work of the Survey.

March 16.—Thomas Stevenson, M.I.C.E., President, in the chair.—Prof. Tait called attention to anticipations of the [illegible] theory, and of synchronism, which occur in a book [illegible] Potentiâ Restitutivâ," published by Hooke in 1667.—Dr. Crum Brown read a paper on the hexagonal system in [illegible] graphy. The forms of the uniaxial system may be [illegible] derived from forms or parts of forms in combination [illegible] regular system by uniform expansion or contraction [illegible] tion parallel to the axis of the uniaxial system, as [illegible] face of the cube for the tetragonal, and normal to [illegible] octahedron for the hexagonal system. Faces, therefore, [illegible] are, in the regular form or combination, at right [illegible] parallel to such axis, retain their relative angular [illegible] changed in the uniaxial form or combination, and [illegible] represented by means of indices referring to the [illegible] of the regular system, whatever be the amount of [illegible] tion (expansion or contraction). Those faces [illegible] parallel to the axis, and basal faces at right [illegible] other faces have their angular position altered by the [illegible] tion. These other faces are pyramidal faces. Each [illegible] lies between, and in the same zone with, a prism [illegible] face. It may, therefore, be represented by the [illegible] $a i + \frac{1}{\rho} b_4$, where i and 4 are the symbols of the prism [illegible] and the basal face respectively, a and b are unit [illegible] and ρ is the ratio of the length of a line parallel to the [illegible] to the length of the line before deformation. When [illegible]

is becomes, for the tetragonal system $(h\,k\,l) + \frac{r}{p}\,n\,(001)$,

$\left(h\,k\,\frac{n}{p}\right)$ the Miller symbol for a pyramid face in
rem, with the ratio of the parameters of c to that of a or y,
ed by p. In the hexagonal system the symbol $r + \frac{1}{p}\,n\,i$
ne form $(h\,k\,l) + \frac{r}{p}\,n\,(111)$, where $h + k + l = 0$. We
ve p understood, as it is constant for the same substance
ne temperature, and write this in the contracted forms
). This gives $h + \frac{n}{p}$, $k + \frac{n}{p}$, $l + \frac{n}{p}$, as the coefficients
and r in the equation of the face referred to the rectan-
es of the regular system. These axes are, of course, not
ographic axes of the hexagonal system, but some advant-
ge from their use. They are rectangular, and therefore
nary formulæ of solid geometry can be used; the symbol
eneral form $(h\,k\,l,\ n)$, where $h\,k$ and l are free to change
nd change sign together, and n changes sign independ-

marked transitional forms between fresh-water and marine animals.—On the existence of limestone at Fusulines in the Morvan geological area, by M. Stan. Meunier.—On some crystals of celestine (sulphate of strontian) discovered near Grauchel (Tarn), by M. A. Caraven-Cachin.

BERLIN

Physiological Society, February 27.—Prof. Busch laid before the Society two preparations illustrative of his investigation into the laws of ossification. The one preparation was of the inferior maxilla of a dog, in which, when the animal was from three to four months old, two pairs of precisely similar grains of shot were inserted, as fixed marks, into holes bored by a gimlet of the same diameter. In order that such marks might be really fixed points from which the process of growth could be studied, it was necessary that the pieces of metal inserted into the osseous tissue should not project beyond the surface of the bone, nor, on the other hand, should they touch on other organs by the growth of which they would be liable to be displaced. In the inferior maxilla of a dog Prof. Busch had made four marks, two on each side, at distances of several centimetres, and then, with an exact pair of calipers, he measured the distances of the four grains of shot from each other. The wounds soon healed, the dog did not seem to suffer the least inconvenience, and after 112 days was killed. The examination of the lower jaw now showed that of the four grains there were only three still remaining, the fourth not being discoverable. The two placed on one side of the lower jaw, in front and behind, showed exactly the same distance from each other as at the beginning of the experiment. The distance of one grain on one side from the corresponding grain on the other had on the other hand grown greater, while the length of the whole lower jaw from the posterior angle to the anterior end had throughout the period in question undergone an increase of about five centimetres. From these results Prof. Busch inferred that the increase in length of the lower maxilla was not due to interstitial growth but to apposition. The second preparation had for its object to ascertain facts regarding the growth of the epiphyses of the long bones whether it proceeded from the terminal line between epiphysis and diaphysis, from the epiphysal line, or from the articular cartilage. For this purpose steel pins, 1 centimetre long, were inserted into previously bored holes, one pin close under the epiphysal line of the tibia, a second in the epiphysis of the tibia, a third in the epiphysis of the femur, and a fourth close above the epiphysal line of the femur. The point of the gimlet was broken off during the operation, and served as a fifth mark. The question as to the mode by which the epiphyses grew was to be decided by the eventual change in the distance between mark 2 and mark 3. The experiment in this case likewise was carried out on a lag dog of three months old, which was killed 119 days after the operation. The examination of the marks then showed that mark 1 was removed several centimetres lower down, lying horizontally under the periosteum. Mark 2 lay apparently unchanged at its original spot; mark 3 was shifted a large piece upwards, and lay horizontally under the periosteum of the diaphysis. As a result of the operation, therefore, instead of under the epiphysal line, it was inserted above that line into the diaphysis; mark 4 was not to be found; mark 5, the broken-off gimlet-point, lay free on the posterior edge of the diaphysis. As to the growth of the epiphysis, the experiment had therefore no significance, seeing that mark 3 was not inserted into the epiphysis of the femur. It showed, however, indisputably that the diaphyses grow by apposition from the epiphysal line, and that in proportion as the parts retired from this line, they became from resorption thinner and slenderer. In the discussion on this communication, Prof. Wolff stated that he had performed a great number of experiments on the lower jaws of pure young rabbits, which, contrary to the results obtained by Prof. Busch, clearly demonstrated the interstitial growth of the bone in question. After he had quite concluded these experiments, he would lay the results before the Society.—Prof. Ehrlich made a communication on physiologically important results he had obtained from his investigations into the susceptibility of the different tissues to colouring matters. If colouring substances—in particular methylic blue—were injected into living animals and then, with the utmost expedition, particular tissues were examined, interesting reactions of the living tissue under the colouring materials would be perceived, which, in spite of their rapid evanescence, revealed important facts which by other methods were in part wholly unascertainable, in part to be ascertained only with difficulty.

After the injection of methylic blue, Prof. Ehrlich found in the submucous tissue of the tongue very numerous fibres and fibrous reticula coloured intensely blue which sent processes to the epithelial formations, and it was easy to determine that these fibres were the axis cylinders of the sensory nerves. These blue-tinged axis cylinders were found very numerously in the gustatory papillæ, at the basis of which they formed a quite narrow reticula network, whence, then, single fibres ending in knots proceeded anteriorly to the ciliated cells. Network of blue fibres were found very copiously and closely in the cornea. The iris likewise showed blue plexuses, particularly on the anterior side; on the posterior side only long cancellated reticula were observed. In the muscles, on the other hand, were found only detached blue fibres, the ending of which in the muscle fibre could not be established. The axis cylinders of the motory nerves were, according to this experiment, not coloured by methylic blue during life; it was only the sensory nerves which reacted to the colouring matter. The vessels, arteries, capillaries, and veins were surrounded by blue plexuses. It could not, however, be decided whether the blue fibres proceeded to the smooth muscle cells. In the retina the nervous layer showed no blue colouring. In the ganglion layer, on the other hand, cells richly charged with blue, and having numerous branching processes, were found, which, too, were in communication with the processes of neighbouring cells. In the mixed nerve stems and in the roots of the nerves no blue fibres were found. The central ends, on the other hand, showed a decided methylic blue reaction, as did also the peripherical ends of the sensory nerves. In the brain blue fibres were found only rarely, but were very abundant in the medulla oblongata, while they were wanting, again, in the spinal marrow, and from these results it appears that the colouring of living organs with methylic blue was a very important means towards observing the endings of sensory nerves in them. It must, however, be borne in mind, that the examination had to be prosecuted very rapidly after the colouring process, because, in living tissue, the colouring material got very quickly—in the course of a few minutes—lost by diffusion, and the colouring of the axis cylinders disappeared.—Dr. Benda laid before the Society several preparations sent by Prof. Adamkiewicz, of Cracau, and gave an explanation of them. After colouring with saffranine, Prof. Adamkiewicz found, in transverse sections of nerve fibres and cords of the spinal marrow within Schwann's sheaths, yellow to brown coloured crescents, which were sections of peculiar fusiform cells, and in the opinion of Prof. Adamkiewicz represented hitherto unknown parietal cells, lying within the nerve fibres, distinguished by their saffranine reaction.

Meteorological Society, March 3.—Dr. Hellmann spoke on the rainfall of Germany. After a short reference to the rain-maps of Germany, hitherto published, which had been in some degree prepared from insufficient material and according to inadequate methods, he set forth the points of view which had determined the arrangement of sixty new rain-stations. By grouping and comparing the new annual observations with those of neighbouring stations, which ranged over a long series of years, he was now in a position to draw a number of important conclusions. He was able to establish, for example, that the eastern part of North Germany, and, in particular, the right bank of the Oder, was not, as had hitherto been supposed, a dry district, at least not over its whole area, seeing that there were several stations within that section showing moderate amounts of rain. It was further ascertained that the views formerly prevalent respecting the rainfall in mountainous regions were not correct, each mountain chain not having been considered separately when inductions were made from the data hitherto accumulated, in which other essential factors came to be mixed up with that of the elevation and vitiated the result. In regard to the yearly distribution of rain, Dr. Hellmann's investigations showed that the great North German plain was embraced within the region of the summer rains; that the curve of rain-quantity and rain-frequency sank from January to April, reaching its minimum in that period, whence it rapidly rose to its maximum, which was attained in the summer months, and then sank slowly to its winter values. The maximum of rainfall in the furthest east occurred in June; immediately to the west in July; still more to the west in August; in Sleswick, later still; and in Heligoland, not till November. A closer examination of the rain-curve in North Germany showed that it consisted of two maxima, with a depression of greater dryness occurring in July. A similar double maximum was likewise found in South Germany and in North-West Germany. The first and greater rain-maximum occurred with recurrence of cold in June, and, altogether, the curve of temperature in North Germany showed a perfectly contrasting, inverse course with that of the rain-curve. The mountains of Germany—the Sudetic Mountains, the Taunus, the Harz, the Thuringian Forest—which were all separately investigated in respect of their rainfall—showed in their course of the yearly rain-curve as compared with that of the plain. In the mountains, the maximum of rainfall occurred in some, while the curve sank in spring, then rose to a small secondary maximum in summer, sank thereafter, and finally rose to the year's maximum in winter. In respect of the absolute maxima the observations hitherto made showed that in the mountains many the month's maximum amounted to about 9·45 inches, that the greatest daily rainfall amounted for the plain to 5·91 inches, and for the mountains to from 7·88 to 9·45 inches. The greatest hourly rainfall hitherto observed was 1·18 inches. Dr. Hellmann exhibited a self-registering rain-gauge by Hottinger, and explained its construction.—Dr. Hellmann described an ascent of the Schneekoppe made by him on June 3 and 4, 1885, and submitted some meteorological observations taken by him on that occasion. On the height of the Schneekoppe he had clear sunshine over head, while the mountains around lay enveloped in fog, the contour of which he was able from his position to observe. In the Riesengrund, one arm of which was curved into a whirling shape, resembling a column of smoke in an ascending air-current, in accordance with Herr Vettin's experiment (*vide* NATURE, vol. xxxi. p. 511). On the Schneekoppe he saw the brown-red ring around the sun in a state of remarkable completeness. It was through yellow and yellow-brown into the copper-coloured, 6½° broad. At the point where it touched the horizon the limbs showed different tints. Before sunrise the horizon was densely surrounded by a violet halo, which extended upwards as far as 18° from the moon, and gradually passed into the blue sky. The observer stationed on the Schneekoppe found that he likewise had often, for now nearly a year, seen the violet halo around the moon. Lastly, it was to be noted that like all other exposed objects, the telegraph poles were covered with immense masses of hoar-frost, so that they showed a diameter reaching to 1 m., and the rain-gauges were also heavily covered with the hoar-frost as in be practically

Neither sugar, saccharum, nor any of the many new Brewing Materials are used in the manufacture of the "S. N." Stout; it is Brewed entirely from the finest Malt and Hops; it is, too, more hopped than Stout is generally; therefore, besides being very nutritious, it is an excellent Tonic and particularly suited for invalids, ladies nursing, or anyone requiring a good strengthening beverage. It is a "Sound Nourishing" Tonic, and very much recommended by Medical men.

WILLIAM CARRUTHERS, Esq., F.R.S., will, on SATURDAY NEXT (April 18), at three o'clock, begin a Course of Four Lectures on "Fir Trees and their Allies, in the Present and in the Past."

Subscription to this Course, Half-a-Guinea; to all the Courses in the Season, Two Guineas.

The GROCERS' COMPANY'S SCHOLARSHIPS for ORIGINAL RESEARCH in aid of SANITARY SCIENCE.

The Scholarships, each of the value of £150 a Year, and open only to British Subjects, are founded with a view to encourage the making of exact Researches into the Causes of important Diseases, and the means by which they may be prevented or obviated. The Appointment and Re-appointment to these Scholarships will be made in the month of MAY next.

Applications to be made during the month of APRIL, by Letter addressed to the CLERK of the Grocers' Company, Grocers' Hall, London, E.C., from whom Copies of the Scheme can be obtained.

UNIVERSITY COLLEGE, LONDON.

CHEMICAL PHYSICS AND INORGANIC CHEMISTRY.

Thirty Lectures will be given by SAMUEL RIDEAL, D.Sc., F.C.S., on Mondays, Wednesdays, and Fridays at 4, commencing April 27.

The Course includes the Subjects for the Intermediate Scientific and Preliminary Scientific Honours Examination, but some knowledge of the Pass work will be assumed. Fee £2 2s.

TALFOURD ELY, M.A., Secretary.

KING'S COLLEGE, LONDON,

MEDICAL DEPARTMENT.

The SUMMER SESSION will begin on FRIDAY, May 1.

In addition to the regular Medical Classes there will be Courses of Lectures and Demonstrations on Botany, Practical Chemistry, Practical Biology, and Experimental Physics, and the Tutors' Class for the Preliminary Scientific Examination and the University of London. There are Special Tutors for all the ordinary Medical Examinations without extra Fees, and Special Classes for the Preliminary Scientific and Intermediate M.B. Examinations of the University of London and the Primary Fellowship of the Royal College of Surgeons. Students entering in the Summer Session will be eligible to compete in September next for the two Entrance Warneford Scholarships of £50, for two Science Exhibitions given by the Clothworkers' Company, and for two Sambrooke Science Exhibitions.

For the Prospectus, apply personally, or by Post-card, to J. W. CUNNINGHAM, Esq., King's College, London.

THE MIDDLESEX HOSPITAL MEDICAL SCHOOL.

The SUMMER SESSION, 1885, will commence on May 1. The Lectures and Demonstrations are arranged with a view to meet the requirements of Candidates preparing for Examination under the new Competitive Scheme.

An ENTRANCE SCHOLARSHIP, value £25, will be offered for Competition to Students commencing their Medical Education in May. The Examination will be in Classics, Mathematics, or Natural Science, and will commence on April 29. Two Entrance Scholarships of the Annual Value of £105 and £50 respectively, tenable for two years, and a Science Scholarship value £35, will be offered for competition at the beginning of the Winter Session.

For Prospectus containing Particulars as to other Scholarships, Resident Appointments, Fees, &c., apply to the DEAN, or the Resident Medical Officer at the Hospital.

ANDREW CLARK, Dean.

ST. GEORGE'S HOSPITAL MEDICAL SCHOOL.

HYDE PARK CORNER, S.W.

The Summer Session will commence on FRIDAY, May 1.

Five Entrance Scholarships—

The William Brown £100 Exhibition;
The Williams Brown £40 Exhibition;
Two Brackenbury Prizes, £52 each;

And various other Prizes, are open to Competition.

Full Particulars, with the Subjects of Examination, may be obtained on application to

WILLIAM WADHAM, M.D., Dean of the School.

ST. THOMAS'S HOSPITAL MEDICAL COLLEGE,

ALBERT EMBANKMENT, S.E.

The Summer Session will commence on May 1. Students who have passed a Preliminary Examination are informed that, under the Regulations of the Examining Board in England, it is an advantage to begin in the Summer Session; those entering in summer are also eligible to compete for the Science Scholarships of £100 and £60, awarded in October.

There are numerous Prizes and Scholarships, and all Appointments are open to Students without extra charge.

Special Classes for the Examinations of the University of London are held throughout the year. A Register of Approved Lodgings and of Private Families receiving Students to reside is kept in the Secretary's office.

Prospectus and all particulars can be obtained from the Medical Secretary, Mr. G. RENDLE.

W. M. ORD, Dean.

LIVING SPECIMENS FOR THE MICROSCOPE

GOLD MEDAL awarded at the FISHERIES EXHIBITION.

LONDON: 11, NEW BURLINGTON STREET.

MUTUAL LIFE ASSURANCE.

SCOTTISH PROVIDENT INSTITUTION.

EDINBURGH—6, ST. ANDREW SQUARE. LONDON OFFICE—17, KING WILLIAM STREET, E.C.

The ATTENTION of ASSURERS is directed to the SPECIAL ADVANTAGES obtainable in this Society, in respect of
ECONOMY—EQUITY—SAFETY.

ECONOMY.—The Premiums are, in many cases, 20 to 25 per cent. under the usual rates, so that a Policy for £1250 may generally be had for the yearly payment which would elsewhere assure £1000 only.

EQUITY.—The whole Surplus is divisible among the Policy-holders themselves, on an equitable principle—no share given to those by whose early death there is a *loss* to the other Members. From this source large additions have been made, and may be expected in the future.

SAFETY.—The Business (which for ten years has exceeded a Million yearly) is of the most select character, and conducted at the smallest cost.

The expenses, which are less than in any Office transacting so large a business, were last year under 9 per cent. of the Premiums, and little over 6 per cent. of the year's Income.

THE FUNDS accumulated from Premiums exceed **£5,000,000**, the increase last year being £333,383.

Only two Offices in the Kingdom (both older) have as large a Fund.

Claims under Policies now payable a Month after Proof.

Reports, with Tables of Premiums, &c., on Application.

J. MUIR LEITCH, London Secretary.

JAMES WATSON, Manager.

WESLEY COLLEGE, SHEFFIELD.

(AFFILIATED TO THE LONDON UNIVERSITY, 1844.)

GOVERNOR AND CHAPLAIN ... ... REV. W. H. DALLINGER, LL.D., F.R.S., &c.
HEAD MASTER ... ... H. M. SHERA, ESQ., M.A., LL.D.
SECOND MASTER ... C. J. SCOTT, ESQ., M.A., Scholar and Priceman (Camb.).
1ST MATHEMATICAL MASTER ... ... THOS. HUGH MILLER, ESQ., B.A. (Wrangler) Camb.

And TWENTY ASSISTANT MASTERS and PROFESSORS.

In addition to Classical, Mathematical, English, and Commercial Subjects, BIOLOGY, PHYSICS, and CHEMISTRY, a Modern Languages of Europe, Hebrew and Syriac, Vocal and Instrumental Music, and Drawing are taught by Accomplished Professors.

The REV. W. H. DALLINGER, LL.D., F.R.S., has undertaken the PROFESSORSHIP of NATURAL SCIENCE; and gives Weekly Lectures and Class Instruction in PRACTICAL ZOOLOGY, BOTANY, &c.

CHEMISTRY is taught by R. W. LANCASTER, ESQ., B.A. (1st Class Nat. Science), Christ Church, Oxford; and a Course of LECTURES on PHYSICS is delivered each Term by A. H. ALLEN, ESQ., F.C.S. SCHOLARSHIPS are AWARDED worth, in the aggregate, 300*l.* a year.

The JUNIOR SCHOOL is in excellent efficiency. Permanent Staff, T. S. COX, ESQ., B.A. (London), and three fully TRAINED Masters. CHEMISTRY, R. W. LANCASTER, ESQ., B.A. (Oxon); MUSIC and SINGING, J. C. MIDDLETON, ESQ., Bac. Mus. (Camb.)

PROSPECTUSES may be obtained by Application to the GOVERNOR or HEAD MASTER.

THE SPRING TERM WILL COMMENCE ON TUESDAY, APRIL 28.

Now Ready, in Crown 8vo, cloth. Price 7*s.* 6*d.*

PROPERTIES OF MATTER.

By P. G. TAIT, M.A., Sec. R.S.E.,

Formerly Fellow of St. Peter's College, Cambridge, Professor of Natural Philosophy in the University of Edinburgh.

CONTENTS.—Introductory.—Some Hypotheses as to the Ultimate Structure of Matter.—Examples of Terms in Common Use as Applied to Matter.—Time and Space.—Impenetrability, Porosity, Divisibility.—Inertia, Mobility, Centrifugal Force.—Gravitation.—Preliminary to Deformability and Elasticity.—Compressibility of Gases and Vapours.—Compression of Liquids.—Compressibility and Rigidity of Solids.—Cohesion and Capillarity.—Diffusion, Osmose, Transpiration, Viscosity, &c.—Aggregation of Particles.

be a task of truly national importance, and one which must sooner or later be undertaken. It is a task befitting the ambition of an enlightened statesman. The Minister who shall succeed in the task will leave behind him in the memories of the nation a monument more enduring than marble.

TIMBUKTU

Timbuktu: Reise durch Marokko, die Sahara und den Sudan. Von Dr. Oskar Lenz. 2 vols. (Leipzig, 1884.)

As we have already intimated, Dr. Lenz is about to set out on a new expedition, the purpose of which is to explore the unknown region lying between the upper waters of the Nile and the northern bend of the Congo. The reputation of a scientific explorer already earned by Dr. Lenz through his researches in the Ogoway basin will be much enhanced by the present work, embodying the results of a very successful expedition to North-West Africa, undertaken in the years 1879-80 on behalf of the German African Society. His original commission was restricted to a visit to Marokko, chiefly with a view to a more thorough survey of the Atlas highlands than had hitherto been effected by recent travellers in that still little known region. But the sanction of the Society was easily obtained to extend the field of his operations, so as, if possible, to embrace the still less known section of the Sahara lying between Marokko and the Niger. Timbuktu, the southern terminus of the caravan routes across this part of the desert, thus became the main goal of the expedition. The famous "Queen of the Wilderness" had been reached during the present century only by three European travellers—Major Laing in 1826, René Caillé in 1828, and Barth in 1853. To these illustrious names must now be added that of Oskar Lenz, who not only entered the place on July 1, 1880, mainly by a new route from the north, but also for the first time made his way thence westwards through the Fulah and Negro States of Mossina (Massina) and Bambara down the Senegal river to the Atlantic coast at St. Louis, capital of the French possessions in Senegambia. Hence the most important result of the journey has been to show that Timbuktu, hitherto regarded as practically inaccessible to Europeans, may be reached both through Marokko from the north and through the Senegal basin from the west.

It will be thus seen that the expedition naturally comprises two distinct sections—Marokko and the Atlas ranges as far as the Draa basin, which are exhaustively dealt with in the first volume; the western Sahara and Sudan described in the second volume, which moreover contains some valuable supplementary matter on the French settlements in Senegambia and on the physical constitution of the Sahara, besides an extremely interesting account of the present political and social relations in Timbuktu. Dr. Lenz travelled with a very small suite, limited to his interpreters, Haj Ali Botaleb and Christobal Benitez, and his trusty Marokkan attendant Kaddur. But, thanks partly to a letter of recommendation from Muley Hassan, Sultan of Marokko, partly to the character which he assumed of a Mussulman physician, he managed to pass without much serious risk through the turbulent and fanatical Arab, Berber, Fulah, and Negro tribes encountered along the route. Hence his success, shared in by some other experienced explorers, that travellers hampered by a minimum of impedimenta are likely to prove more successful in Africa than elaborately equipped expeditions, at least where the object is mere geographical discovery rather than extensive zoological and ethnographic collections.

From the observations made at various points [illegible] times it has become more and more evident that the Sahara can no longer be regarded as having been a marine basin at least since the early Tertiary epoch. The theory may be said to have received its coup de grâce from Dr. Lenz, who plainly shows that the whole of the western section traversed by him is not a depression, as has been assumed, but an irregular plateau rising in the north at a mean elevation of from 800 to 1000 feet, and even at Taudeni, its lowest level, still maintaining an altitude of 400 or 500 feet above the Atlantic. The surface is varied with stony and sandy tracts, the so-called "areg" or "igidi," which have nothing in common with marine sedimentary deposits, but have, in fact, been produced by the weathering of sandstone, quartz, and carboniferous limestones, which appear to be the prevailing formations. It is thus evident that this part of the [illegible] has been dry land for vast ages, and the same conclusion must be inferred from the numerous dried-up water-courses, whose deep channels are distinctly the effects of erosion. These wadies, many of which seem to have been flooded within the last few thousand years, [illegible] from the central highlands north and north-east to the Mediterranean, east to the Nile, south to the Tsad and Niger, west to the Atlantic. Hence down to comparatively recent times the Sahara was a well-watered and wooded region thickly inhabited by agricultural and pastoral communities, themselves the descendants or successors of still more primitive peoples, the contemporaries of Palæolithic and Neolithic man in other parts of the globe. In the Taudeni district, about 20° N., and on the meridian of Timbuktu, Dr. Lenz discovered [illegible] ments of hard greenstone well worked and polished, similar objects have also been found by Gerhard Rohlfs as far west as the Kufara oasis south of Tripoli. The Asiatic camel is here a comparatively [illegible] truder, preceded by the Garamantian wardens and by the elephant, trained also to war by the native Nubians and Phœnician Carthaginians. The [illegible] survives in many of the pools and lakelets [illegible] marking the course of mighty streams, which [illegible] sent their perennial floods down to the [illegible] marine basins.

Apart from possible cosmic influences, [illegible] tributes the great change that has taken place [illegible] historic period, not with Peschel to the dry [illegible] Polar winds, which in the Sahara yield to the [illegible] northern and north-western atmospheric [illegible] largely to the reckless destruction of the [illegible] at one time covered vast tracts in this now [illegible] treeless region. With the vegetation disappeared [illegible] moisture; all the large fauna became [illegible] settled populations were succeeded by [illegible] Berber (Hamitic) stock, joined later on by [illegible] the Arabian Peninsula.

f Timbuktu Dr. Lenz gives on the whole a satisfactory unt. During his residence in the place from July 1 ly 18, 1880, he was hospitably entertained by the ia, a sort of "Burgomeister," or civil magistrate, who ayor, aldermen, and town council all rolled into one, who possesses no political authority whatsoever. e its capture by the Fulahs in 1826, when the fortifi- ns were razed, Timbuktu has been a purely com- ial town, a general emporium for Western Sudan, to all comers—that is, to all the "Faithful," but un- iately a constant bone of contention between the Tuarik (Berber) and Fulah tribes of the surrounding . At the time of Dr. Lenz's visit, the Tuariks, their "Sultan" Eg-Fandagumu, were in the dant, but, beyond levying dues on the imports and ts, neither they nor the Fulahs ever interfere in the administration, which is left in the hands of the . This office itself is hereditary in the Moorish of Er-Rami, originally from the South of Spain, known as "Andalusi," and settled in Timbuktu the sixteenth century. The present Kahia affects le of "amir," and is said to be aiming at the sovereign by making himself independent of the Tuarik and factions. In this he appears to be encouraged by rench, who have lately reached the Niger at Segu, who have quite recently induced him to send an y" to Paris.

ing the journey from Timbuktu to the Senegal Dr. saw a good deal of the Fulahs, who are now every- interspersed among the Negro populations from i and Darfur to Senegambia, and to whom appa- belongs the future of Central and Western Sudan en the Niger and Wadai. Unfortunately, in discussing gin of this mysterious race, he revives the now ex- theory of a "Nuba-Fulah" family, first suggested edrich Müller, the learned but somewhat venture- Viennese ethnologist. At least Dr. Lenz goes so to say that, "touching the ethnographic position of eople Friedrich Müller has probably hit the mark ping together the Nubas and the Fulahs, whom lectively calls Nubas, and divides into a western astern section" (p. 261). This might not be in surprising but for the fact that he further on to the writings of G. A. Krause on the subject. Krause distinctly separates the Fulahs from the , or rather ignores the connection altogether, and hem to the Hamites, calling them "Ur- oder Proto- n." It may be added that with the materials ailable (Lepsius, Nachtigal, Faidherbe, Newman, Reinisch, &c.), it seems possible to determine tual relations of all these peoples with some show ability. But in any case the Fulahs are certainly bas, nor are the Nubas Hamites.[1] Whether is right in affiliating the Fulahs to the Hamitic "mag dahingestellt werden," at least pending information. The type is distinctly non-Negro. from it in almost every racial characteristic— formation, complexion, texture of the hair, figure, ion of members, mental qualities. Dr. Lenz, who nerous opportunities of studying full-blood speci- as amazed at their striking resemblance to Euro-

[1] Here the reviewer must refer the reader to his "Egyptian Sauntord, 1882.

peans, and describes them as of light complexion, with slightly arched nose, straight forehead, fiery glance, long black hair, shapely limbs, tall slim figures, great intelligence. At the same time, since their diffusion among the Sudanese populations the Fulahs have become much modified by crossings with the Negroes and Arabs. "No territory or state is now found exclusively inhabited by pure Fulahs, who are everywhere intermingled with Negro and Arab communities" (p. 259).

The work is illustrated with some good woodcuts and plates, mostly from photographs and sketches by the author, who has also added a general map of the region traversed, and as many as eight carefully prepared itineraries of its several sections. A. H. KEANE

OUR BOOK SHELF

Physical Arithmetic. By A. Macfarlane, D.Sc. (London: Macmillan and Co., 1885.)

THIS is a very thorough work, and one admirably adapted for the use of physical students: indeed, we think so well of it that we would recommend it for use in all schools and establishments where the subjects of which it treats are taught. There is a great amount of matter, tersely put and aptly illustrated by copious worked-out examples, and, in addition, there is good store of exercises to try the pupil's strength. Answers are appended, and a useful index crowns all.

What is its subject-matter? It treats, we should say, *de omni scibili*, and perhaps *de quibusdam aliis*. But to descend to particulars: there are nine chapters, and in these are discussed matters financial, geometrical, kinematical, dynamical, thermal, electrical, acoustical, optical, and chemical. Have we not rightly described its subject-matter above? Dr. Macfarlane has done much good work in other directions, and in this particular direction he gives us, not the result of two or three months' turning over of text-books, but what he has noted down since his student days; hence he speaks of what he does know. A diligent student, an original researcher, he has learned and assimilated methods arrived at by such masters in physics as Thomson, Maxwell, Tait, Everett, and Chrystal, and put them together here in orderly method. This method the author calls the *equivalence* method. "Each quantity is analysed into unit, numerical value, and, when necessary, descriptive phrase. The rate, or law, or condition, according to which one quantity depends on one or more quantities, is expressed by an equivalence. These equivalences are of two kinds—absolute and relative; the former expressing the equivalence of *dependence*, the latter the equivalence of *substitution* or *replacement*."

We cannot give a brick, but we feel sure that the edifice to which we liken the book will be found to be constructed on thoroughly sound principles, and that no student who buys it on our recommendation will regret having done so.

It would take a very long time to test the furniture (*i.e.* the examples); upon its suitability, we cannot now pronounce an opinion; moreover, each student will have his own particular room to explore: after a visit to all the rooms, each appears to be quite *comme il faut*.

Coordonnées parallèles et axiales. Méthode de Transformation géométrique et Procédé nouveau de Calcul graphique, déduits de la Considération des Coordonnées parallèles. Par Maurice D'Ocagne. (Paris: Gauthiers-Villars, 1885.)

Two fixed points, *A*, *B*, called the *origin of co-ordinates*, are taken, and through them are drawn two parallel straight lines, *Ax*, *By*; these are called *axes of co-ordinates* (or co-ordinate axes). Lengths, *AM*, *BN*, measured on

these lines, upwards positive, downwards negative, are the *co-ordinates* of the straight line *MN*. So much for the *parallel* co-ordinates. Take a straight line, *Ox*, for *axis*, and on this line a point, *O*, the *pole* of the system. A straight line is determined by the angle θ, which it makes with the axis, and by the length λ from *O* of its intersection with *Ox*. These are the *axial* co-ordinates. Elementary details of these two systems are given for the former in Chapters I.-V. (pp. 1-33); for the latter, in Chapters VI.-VIII. (pp. 36-43). Several applications to examples are discussed. Chapters IX., X. (pp. 52-73) are devoted to a "Méthode de transformation géométrique fondée sur la simple comparaison des coordonnées parallèles avec les coordonnées rectangulaires." The "procédé nouveau" is the closing portion of this chapter (pp. 73-82).

The illustrations in the pamphlet are mostly taken from curves of the second degree, but these co-ordinates—a kind of tangential co-ordinates—are useful for such questions as the following:—Find a curve such that a portion of a tangent intercepted between the point of contact and the axis has a constant length (the tractrix is such that the area between it and the axis is equal the area of a semi-circle, radius equal distance from origin to cusp of tractrix); find a curve such that the portion of a perpendicular *TI* to the axis *Ox* drawn through the foot *T* of the tangent, limited on one side by *Ox* and on the other by the corresponding normal, has a given length (the curve, of course, is readily seen to be a cycloid).

The pamphlet is an interesting one, and suggests methods of procedure which in some cases have advantages over other methods more familiar.

LETTERS TO THE EDITOR

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts. No notice is taken of anonymous communications.

[The Editor urgently requests correspondents to keep their letters as short as possible. The pressure on his space is so great that it is impossible otherwise to insure the appearance even of communications containing interesting and novel facts.]

The Colours of Arctic Animals

I AM sorry that I cannot agree with my friend Mr. Meldola as to the insufficiency of the explanation of the white coloration of Arctic mammals and birds as due to protective adaptation, since it appears to me that there is no important group of facts in natural history of which the explanation is more complete; while on the other hand I venture (though with some hesitation) to question the basis of his counter explanation, as I am not aware of any sufficient proof that colour, *per se*, affects the radiation of low grade heat. At all events I feel tolerably certain that this cause, if it exists, has had no perceptible influence in determining the white colours of Arctic animals.

I am not myself aware of there being "many species" possessing the white coloration as to which there is any difficulty in seeing the advantage they may derive from it, and there is certainly a large body of facts showing that *colour* is, in almost all animals and in every part of the world, more or less protective or adaptive. If the white coloration of Arctic animals stood alone, it might be thought necessary to supplement the protective theory by any available physical explanation, but we have to take account of the parallel cases of the sand-coloured desert animals and the green-coloured denizens of the eververdant tropical forests; and though in both these regions there are numerous exceptional cases, we can almost always see the reason of these, either in the absence of the need of protection or in the greater importance of conspicuous colouring. In the Arctic regions these exceptions are particularly instructive because in almost every case the reason of them is obvious. Let me call attention to a few which now occur to me.

In the Arctic zone the wolf does not turn white like the fox, the reason evidently being that he hunts in packs, and concealment from his prey is not needed. So the musk-sheep and the yak, though both exposed to the extremest cold, are not white, because they are both swift and strong and need no concealment from their enemies. For the same reason neither the reindeer, nor the caribou, nor the reindeer are wholly white. The glutton and the sable are dark-coloured, though they inhabit the coldest regions, and this is clearly because they are enabled to are better concealed from their prey by a dark than a light colour. If any useful protection from cold were to be derived by a white coat, we should expect it to appear in such cases as the Esquimaux dogs, exposed for countless generations to the severest climate. But they gained the required warmth by thickening of the woolly undercoat in winter, as do most other animals; and this suggests the general proposition that it will be always easier and safer to gain warmth in this way than by modification of colour, which could certainly have but a very small effect, and might often interfere with other and more greater importance. Exactly analogous cases occur among birds. The raven is, perhaps, the extremest Arctic species, but feeds on carrion, it has no need of concealment in approaching its prey, and thus it keeps its jet black coat in the depths of Polar winter.

The physical explanation of melanism in butterflies and other insects, on the other hand, seems to me to be probably a sound one; but even that requires more evidence and a wider knowledge of the habits of the species before we can consider it as proved. It may be that the dark colouring is protective by assimilating with the surroundings of the insect when at rest, and this can only be decided by observations specially directed to the point in question.

But even if, in this case, the dark colour has been gained in order to favour the absorption of the direct rays of the warm sun, it affords no support whatever to the totally different case in which the radiation of the obscure heat from an animal body has to be checked. I may, perhaps, be ignorant on the point, as it is rather out of my line, but I am not aware of any experiments to determine the influence of colour *per se*, apart from the structure and surface-texture of coloured substances, on the radiation or absorption of heat of a low grade of temperature and from a dark source. The only authority I have at hand (Ganot's "Physics," eighth edition) seems rather to show that colour has no effect in such cases, for I find it stated at p. 352, that the radiating power of *lampblack* and *vermilion* are both being given as 100, while *Indian ink* is only 88. Again, at 100, the source of heat being copper at 100° C., while that of Indian ink is given as 85. This seems to show that mere texture or molecular structure is the important point and colour has no effect whatever.

In order to determine experimentally whether white feathers are inferior to black as radiators of animal heat, I did not do to employ stained or dyed materials, because the process employed might affect the texture of the surface, and produce effect not at all due to the colour. A fair test would be afforded by two samples of cloth or flannel woven from white and from natural wool respectively, the wool to be obtained from the same breed of sheep, and, if possible, from the same animal, while the material must be as nearly as possible identical in weight and texture. I shall be glad to learn from Mr. Meldola or any other of your readers, whether any experiment of this kind has been made, or whether there is any valid reason for believing that the radiation of animal heat is at all affected by colour alone.

ALFRED R. WALLACE

Civilisation and Eyesight

THE statistics of eyesight given by Mr. H. J. Gupp in NATURE (p. 503) relating to the inhabitants of the Bahama Islands as tested by the Army test-dots, bring us nearly [illegible] to the solution of the question of the relative acuteness of vision of civilised and savage races than any previous investigation which has appeared in your columns, as we are able to compare them with statistics obtained under similar conditions in this country. The Anthropometric Committee of the British Association gave a series of tables in their Report for 1880 showing the results of their inquiries into the sight of different classes of the community, carried out by means of the Army test-dots and for the purpose of comparison with Mr. Guppy's figures I have extracted the returns relating to men employed in agricultural and other out-door occupations as most nearly agreeing with the conditions of life of savage people, and have collated them together with Mr. Guppy's, in the following table:—

Distance in feet at which the Army test-dots were distinguished	English agricultural and out-door labourers, age 16 to 45 years. No. of obs.	Solomon Islanders, age not stated. No. of obs.	English agricultural labourers, &c., age 21 years. No. of obs.

cavities of the vesicular parts of the rock were often filled by calcite or hematite.

The apparent absence of any cone or cuff deposit, the compact and columnar structure of the rock, and the vertical position of the columns, seemed to show that the whole had been originally one continuous sheet of submarine lava-streams, which had been subsequently elevated and cut up by the waves into the several islands—a conclusion which was supported by two other circumstances: the form of the islands and the shallow intervening depths (6 to 9 fathoms).

It is noteworthy that several of the islands sloped away gradually west-south-west to south-west, a direction coinciding with that of the submarine slope in this part of the Formosa Channel. From this circumstance it would seem that the succession of lava-streams flowed in a north-west direction, and that their source lay in the north-east portion of the group.

A New Bird in Natal

SOME months ago, Mr. Ferreira, a member of my congregation, informed me that he had shot some time previously a bird in the early morning which neither he nor any of his neighbours had seen before. From his description of it I concluded that it probably belonged to the goat-suckers, and on examination of the skin I find that the supposition is correct.

A day or two ago he brought the skin to me: it had been stretched against the wall of his room to display its plumage to the greatest advantage. The measurements which I give cannot therefore be perfectly accurate. One of its long plumes has been broken by a pellet, but otherwise the skin is in tolerably good preservation, and I trust that it may be well stuffed and set up, for the bird is certainly not mentioned in the first edition of Layard's "Birds of South Africa," nor yet in any of the books or catalogues in my possession, and the bird is in itself so very remarkable that one cannot help thinking that it would have been described in the books I have had it been known. I will deposit the skin in the Natal Museum, Pietermaritzburg. The bill is that of a goat-sucker, strongly fenced with strong hairs. The length of the body from tip of the bill to the insertion of the tail is 6 inches; length from tip of bill to tip of tail, 11½ inches; length between tips of wings—probably stretched to—much—24 inches.

The colour is the usual brown of the family—bars on the tail of brown black, and mottled bars of light and dark brown; feathers, eight in number, the longest on the outside of the tail.

Wings: Primariæ, 9 in number.

Length of the 1st feather,	7½	inches.
,, 2nd ,,	about an inch shorter.	
,, 3rd ,,	shorter than second; the following three about the same length as the 3rd.	
Length of the 7th feather,	7½	inches.
,, 8th ,,	11½	,,
,, 9th ,,	27½	,,

The first seven of the primaries are tipped with white, the 2nd and 3rd rather broadly, the 1st scarcely. The 8th becomes greyish towards the tip, and the ribs of the 7th and 8th are brown, while the others are black. Two-thirds of the length of these feathers are black; but a band of white, narrower on the first and increasing to about 3 inches broad on the 8th feather, extends along the roots and middle of them, and crosses over to the 9th long feather, which, for 21 or 22 inches, is of a dullish silver-gray. The secondariæ are tipped with white, with the exception of the 1st and 2nd, which only give indications of being so; they are generally black-brown, with markings of light brown. There is a reddish ring around lower back part of the neck.

The breast is light gray, generally with light brown markings in bands.

Its feet are those of a goat-sucker, but on comparing the foot of the *Caprimulgus europæus*, as drawn by Van der Hoeven (vol. ii. plate 7, Fig. 9, ed. 1858) I find the tenth of the comb of the middle toe much broader and stouter than that of the former. There are only four teeth, with a smaller or false one at the root of the nail. The length of the nail is about one-eighth of an inch, and the breadth of tooth is therefore about one-sixteenth of an inch.

This bird is evidently very closely related to the pennant-winged night jar, or long-shafted goat-sucker (*Macrodipteryx afrinana*); but the markings are very different, and the long-shafted feathers are not more than 17 inches long, while those of the latter are more than 27 inches in length, and they do not depart in inclination to form a long naked shaft, but are evidently webbed on both sides from the root to the tip.

It is very singular that this bird should only have been known in this district in 1884. The Bushmen are also there as also are the Kaffirs, but no one has ever seen it. It is more singular since it was shot on a farm that has been occupied, and that by a farmer who in his younger days was accustomed to help collectors of birds for our home museums. Perhaps the long and severe drought, which will prevail this year in the interior, may account for its presence in Natal.

Pasturie, Grey Town, Natal, March 2 JAMES DIXON

C. T. E. VON SIEBOLD

CARL THEODOR ERNST VON SIEBOLD was born at Würzburg, in Bavaria, on February 16, 1804. His brother was the well-known traveller and physician. Carl was brought up chiefly, under the superintendence of his father, for the medical profession, and he carried on practice for a few years as a physician at Danzig and Königsberg. In 1835 he received the appointment of Master of the Lying-in Hospital at Dantzic. Early in life he showed an interest in zoology, and in 1840 he removed from Dantzic to Erlangen, where he studied comparative anatomy, zoology, and veterinary science. In 1845 he was appointed Professor of Zoology at Königsberg, and shortly afterwards he made a prolonged sojourn on the Adriatic. At this time he studied with immense zeal and ardour at the anatomy of the lower invertebrates, and as the result of this work and his lectures combined he commenced the elaboration of his well-known "Lehrbuch der vergleichenden Anatomie der Wirbellosen Thiere." In his preface to this work, which has been translated into English and French, he insists on the importance of a knowledge not only of the adult anatomy but also of the developmental stages of the animals described. Generous aid in the completion of the work at the time most excellent treatise was given to him by C. Vogt, H. Stannius, A. Krohn, H. Koch, and A. Kölliker, and in 1849 he founded, in connection with the last-named of these eminent biologists, the *Zeitschrift für wissenschaftliche Zoologie*, a journal which has ever held a leading position among the scientific publications of our day, and one which is still known and esteemed wherever zoology is studied.

In 1850 von Siebold was appointed to the Professorship of Physiology in the University of Breslau, and also received the charge of the Physiological Institution of the city.

In 1853 he was appointed Professor of Zoology and Comparative Anatomy in the University of Munich, and Director of the Zoological and Zootomical Cabinets of the city. These positions he filled during the remainder of his life.

Shortly after his appointment to the Munich Professorship he commenced an elaborate series of investigations into the vexed question of "Parthenogenesis," treating the subject with a belief that facts had been entirely misstood; and his treatise on this phenomenon, as found by him to actually exist in bees and moths, was a great contribution to science. This work was published at Leipzig early in 1856, and was translated by the Ray Society the following year into English.

Somewhat earlier in date he published a memoir on "Tape and Cystic Worms, with an introduction on the Origin of Intestinal Worms," which was deemed worthy of being translated into English, by Prof. Huxley, for the New Sydenham Society. The good that this translation effected by introducing some scientific facts to the notice of our medical men it is not easy to calculate.

In 1858 the Royal Society elected him as one of their honorary members. In 1865 he was made a Correspondent

g member of the Institute of France. There seems tle need to enumerate all the honours that were conrred on him during the half century that he was known one of the distinguished zoologists of Europe.

In the important and indispensable catalogue of Scienic Papers published by the Royal Society, we find a t of over 130 memoirs ascribed to Prof. Von Siebold.

Failing health during the last few years interrupted this, to 1874, steady flow, and Dr. Ehlers undertook much the labour of editing the *Zeitschrift*. Those who had personal knowledge of Von Siebold will remember his easant and friendly manners, the readiness with which placed at the students' disposal all the information in s power, and the visitor to the Zoological Museum at unich will not soon forget the vast stores, not only llected, but scientifically arranged under the supertendence of Von Siebold.

THE EGGS OF FISHES[1]

II.

THE condition of the fish-fauna of the various grounds may be estimated to some extent by the number of e floating ova near the surface. We have seen that Sars und the water crowded with the multitude of ova off e Loffoden Islands, where enormous numbers of cod e captured. In our seas no fishing-bank is so prolific, e greatest number of ova occurring on Smith Bank, off aithness, and the next on the rich grounds off the Island May—both of which present a great contrast with the eagre supply of eggs of round fishes floating in our own ay. The proportional numbers in each case accord very ell with the captures of adult cod in the several areas.

No sight can be more interesting to the naturalist than e surface of the sea, in the condition just mentioned, out the beginning of April. The rough water of the eat fishing-grounds—such as off Smith Bank, and mewhat further from land—is enlivened by large groups gulls, guillemots, and the ubiquitous gannets, apparently feeding on the smaller fishes which have been tracted to the surface by the wealth of food. At short tervals the long dorsal fin of a large killer appears ove the surface, and the water behind it is churned into am by the powerful strokes of its tail; while a small oup of bottle-noses (another kind of toothed whale) is cognised by the noise and foam, as one or more leap om the sides of a huge wave. The tow-net collects rge quantities of ova and minute fishes which have just caped from the egg. It further shows that innumerable inute crustaceans, such as Copepods (*e.g. Calanus finarchicus*, Gun., and *Temora longicornis*, O.F.M.), multides of the young, or nauplius-stage, of sea-acorns, agittæ, and peculiar Annelids (*Ioida*) are present. It is ident, therefore, that the young fishes are placed in the idst of a rich surface-fauna, the more minute forms of hich would readily serve as food.

In the foregoing remarks on the floating eggs of British od fishes, those of the cod, haddock, and whiting, have en chiefly alluded to. We shall now refer to others, ther wholly or partially unknown till this year. I have ready mentioned that Sars found certain floating eggs ingled with the former on the surface of the sea, and entified the young, after hatching, as gurnards. In the esent case the eggs were removed from the adult gurrd, and hatched at St. Andrew's in about a week, so at a further step has been made. The eggs of the rnard float as buoyantly as those of the cod and ddock, but they are considerably larger. Each has a ry distinct oil-globule opposite the germinal area, which nerally is directed downwards. Some are of opinion that the floating of the eggs of such fishes as we are now considering is due to the oil-globules, but the eggs of several fishes, *e.g.* those of the salmon, have a larger quantity of oil, and yet they do not float. The specific gravity of the eggs is slightly less than that of the sea-water; but the precise connection between the floating of the living ova and the sinking of the dead has yet to be made out. Such would form, indeed, a most valuable and interesting subject for investigation at the Marine Laboratory. So easy is it to hatch the eggs of the gurnard that the water in the instance just narrated was not changed. The rapidity with which the development of the embryo goes on in the egg is remarkable, for in 7 or 8 days the young are extruded, whereas in the salmon, for instance, no less than 60 days are required even in a room with a temperature much higher than that of the open air. If the eggs of the salmon are permitted to hatch in an ordinary river, a period of from 95 to 120 days is usually necessary for hatching. The very great difference, therefore, between the marine and fresh-water fishes in this respect is apparent.

The only flat fish in which the ova had been found to float was the plaice, which Dr. Malm had examined in the Baltic. In May of this year, however, the eggs of the common flounder in St. Andrew's Bay showed the same feature. They floated buoyantly on the surface of the water. Prof. Huxley at this time having suggested that perhaps the floating or sinking of the ova was a question of temperature, the eggs of this species were used in some experiments. They had been removed from the fish on May 2, and placed in the Marine Laboratory. On the 5th the majority still remained on the surface, those on the bottom having been carried down by the attachment of sand-grains. A number from the surface were placed in a test-tube. After standing an hour the majority were floating on the surface, one or two lay on the bottom, while others rested in mid-water. Placed in a vessel of water at 98°, the eggs exhibited lively movements for several minutes, being carried up and down by the currents, but never remaining at the bottom. The test-tube felt quite warm to the touch, yet the eggs floated, and remained floating, as buoyantly in the warm water as in the cold, so that their floating in the sea is not a question of temperature.

An interesting sequel, further, remains to be told in connection with this experiment, in which the test-tube had been placed aside and forgotten. On May 10, while explaining the matter to Prof. Ewart, he noticed motion in the test-tube, and I found that the eggs which had been raised to a temperature of 98° had given birth to little flukes, which thus survived the exigencies of their surroundings, both as regards temperature and water. These little creatures are as symmetrical in outline as the young cod or haddock, an eye being placed on each side of the head, while in the adult flounder, as you are all aware, both eyes are on one side (the right or coloured one). The pigment is quite different from that of the young cod, being of a peculiar pale olive or brownish yellow by transmitted light, and the cells seem to be less branched. Their motions also diverge from those of the cod, for the little creatures hang head downwards in the water, either perpendicularly or obliquely, the yolk-sac being on the upper line of the slope. They then move upward, hang as formerly, or slowly descend, repeating these motions frequently. The young cod, on the other hand, dart nimbly about near the surface of the water, and bear themselves quite differently.

But to return to the ova. Before the summer that has just passed, it was not known whether the ova of the turbot, sole, and lemon-dab—all important and valuable food fishes—floated or sank. Accordingly such fishes were a source of special interest. It was not till the end of June and in July that perfectly ripe turbot could be procured, and then the small ova were found to float as

[1] Introductory Lecture delivered to the Class of Natural History in the University of St. Andrews, on November 10, by Prof. McIntosh, LL.D., F.R.S. Continued from p. 536.

buoyantly as any of the foregoing; and the same was proved to be the case with the eggs of the sole and lemon-dab—all these, moreover, being obtained in the act of spawning far out at sea, and in comparatively deep water. The ova of the long rough dab and the common dab were also added to the list of those with floating eggs. The notion, therefore, that such fishes seek the shallow water for the purpose of spawning is visionary, and mainly rests on the preconceived opinion that the eggs are deposited on the bottom.

Amongst the eggs of the cod floating on the surface of the water off the Island of May, in April, were vast numbers of very young sand-eels. The late Mr. Buckland states that they spawn in "May, June, and September," and that they deposit their eggs in the sand. They would rather seem to spawn in spring, and their eggs probably avoid the sand as much as possible by floating on the surface of the water. Sand is a most objectionable site for the eggs of certain fishes, and no less so for the embryo.

Without going into further detail, it is evident, therefore, that the eggs of many of the most valuable food fishes thus float near the surface of the sea, *e.g.* those of the cod, haddock, whiting, bib, and other Gadoids, mackerel, gar-fish, red mullet, weever, plaice, long rough dab, common dab, lemon-dab, sole, common flounder, and probably sand-eels. There is hardly a marine fish, excepting those of the herring group, which appears in our markets, but has this remarkable provision in regard to its eggs. It would also appear that some of these eggs range throughout the water, so as to be caught by a tow-net sunk many fathoms beneath the surface.

There can be little doubt that this wonderful provision is one of the main reasons why such marine fishes have held their own in the struggle for existence—not only with respect to their predatory neighbours, but still more in regard to the persistent inroads on their numbers made by man. Marine fisheries have hitherto been conducted as if practically inexhaustible, both lines and trawlers taking as much from the sea as possible, while no margin has ever been afforded the spawning fishes.

Let us for a moment glance at the working of this arrangement. The comparatively small eggs of the chief food fishes rise to the surface, or nearly to the surface, wherever the shoals of adult fishes happen to be feeding, and this occurs not during a brief period, but it extends over a considerable space of time. The tiny young in their helpless state are carried, along with multitudes of eggs, by every tide into sheltered creeks and bays, in the shallow water of which they find both safety and food. We are familiar with these tiny embryos, furnished with a yolk-sac—and so fragile that they would fall an easy prey to hosts of swimming crustaceans on which, in the adult state, they would hardly deign to feed—near the surface of the sea; but a hiatus yet remains in the history of the young cod, for instance, between the date of complete absorption of the yolk-sac and that in which it is found swimming in the forests of tangles in the laminarian region—for example, off the Castle and Pier Rocks, or even venturing into the harbour. There, as a rule, it is free from the pursuit of both liners and trawlers, and quietly grows apace, feeding on the swarms of minute crustaceans and the myriads of very young mussels which characterise such a region. In the early part of the season they range from one and a half to two inches, and are variegated with a series of pale spots, somewhat rectangular in outline. The general colour is olive, lighter or darker according to circumstances, though a few of the larger examples have a reddish hue, such as signalises the "rock-cod" of the liners, but the pale spots are similar. Many of these young cod are infested by parasitic crustaceans (*Chalimus*), which adhere by a long median process that penetrates the skin. They are accompanied in the laminarian region by the young of the coal-fish, whiting, pollack, suckling, long-spotted [illegible] and lump-sucker.

Sars is of opinion that the intermediate stage—[illegible] which, as above-mentioned, our knowledge is imperfect—is passed by the young cod-fish in the shelter of the [illegible] fishes, on the rich grounds off the Lofoden Islands. It is true that once or twice young cod, of the intermediate stage, and coal-fish have been caught in our seas in the tow-net in July, but the result of the present observations gives no support to this view. The jelly-fishes in our seas are not in sufficient numbers at the time of the intermediate stage, especially in regard to the spawning in April, to act as shelter-forms to the young fishes. It is probable that as soon as they gain sufficient strength to withstand the force of the ordinary ebb-tides, they retire amongst the tangles and other seaweeds of our rocky shores, to which they have meanwhile been carried by currents. While a few, therefore, are found here and there near the surface of the sea amongst other pelagic types, the majority of those in the intermediate stage probably swim somewhat deeper.

The after-history of the little cod of one and a half to two inches, which are found in considerable numbers off the Pier and Castle Rocks in the beginning of July, appears to be as follows. They remain in the littoral region for some months (many being captured even during this season), and rapidly increase in size on the rich and abundant food placed within easy reach. Moreover, it is probable that in this region they are much less subject to the attacks of predatory fishes than in the open sea. We find, indeed, that, while young haddock and whiting abound in the stomachs of cod, haddock, gurnards, and other fishes, it is rare in our seas to find young cod of the size we are now considering. Prof. Sars, on the other hand, procured them abundantly in the stomachs of the pollack (a fish which swims high) off the Norwegian shores; but it has to be borne in mind that they form a chief feature of the young fish-fauna of the region at the time indicated. As they grow larger and bolder they seek deeper water, and are found in numbers over rocky or rough ground, such as off the Bell-rock, and the Bass Carr rocks, and indeed all along the rocky eastern shore. They then mingle with their progenitors on the offshore fishing-banks, and are caught in numbers by both line and trawl. The main cause of this migration from the shore seawards is probably the nature of the food, which, as the animals grow older, becomes of a different character, the larger Crustacea especially—such as hermit-crabs, Norway lobsters, and many short-tailed crabs—being eagerly sought after, along with various kinds of fish. So far as our knowledge at present goes, a cod probably takes between three and four years to attain full growth.

A feature which requires special mention is that, while the shoals of young cod are watched at any of our eastern shores during several months, one is struck by the fact that throughout the period many small forms are present that is, some do not appear to have grown; but we have seen that the spawning of the adult fishes extends over a considerable period, and, further, that only a portion of the eggs in any given fish come to maturity at once. There is thus a succession of young fishes becoming at a certain stage shorewards, and again migrating outwards. This and other facts already mentioned show how intimately the in-shore ground depends on the off-shore; in other words, the eggs and very young fishes are carried from the offing by every tide during the season, while a constant stream of young fishes of a certain size goes to swell the ranks of the adults beyond the three-mile limit. The prosperity of the one region is thus intimately associated with that of the other.

In this rapid sketch, then, it will have been seen how complex are the relations which surround the [illegible] of marine fishes. Conspicuous above all others, however, is the remarkable provision [illegible]

all the chief food fishes, except the herring group, t or near the surface of the water—so that they are d hither and thither by every surge of the tide, or steadily borne by the deeper currents to stock anew sted waters. The minute and imperfectly-developed os and the delicate young, moreover, are conveyed egions best suited for their future growth and well-

Further, we cannot but be impressed by the fitness arrangement which ordains that these young fishes laced from the first amidst a rich surface-fauna of e forms which serve them as food. These range from icroscopic Infusoria, which cause the crest of every at the ship's side to sparkle with light and the ets to gleam like tunnels of fire; the wonderful , or painter's easel-like larvæ of star-fishes, swarms val sea-acorns, Copepods, and the beautiful zoëæ of igher crustaceans. Besides these, are the peculiar ndiculariæ and Sagittæ, and countless myriads of mussels, which in summer crowd the surface of St. ew's Bay, and at a still later stage, as they are for- g their pelagic existence to settle on the stones and eeds, form the food of the more advanced young haddock, whiting, coal-fish, pollack, and others that shelter for a time amidst the shaggy belt of tangles cling the rocks. The latter thus in their larval state, urishing in their profusion the delicate young of the fishes, in a sense repay the wise conservancy bestowed e Town Council of this city on the fine mussel- of the Eden. It will, moreover, be observed that ot only the eggs of the higher marine animals which but that for a long time zoologists have been familiar the pelagic eggs and young of many invertebrate s of importance. How else, indeed, could the itous mussels, the sedentary oysters, and the equally nary sea-acorns and barnacles be spread throughout cean? Moreover, not only do these swimming larval nourish the very young food-fishes around them, directly or indirectly, but as they—for instance, the crabs, lobsters, star-fishes, and mussels—grow larger older, a kind of rain, so to speak, of such forms place from the surface to the bottom, which is ly taken advantage of by the larger fishes, and thus onderful cycle is completed.

nally, I need not point out to you the importance of the ne Laboratory, to which I have already alluded, and ich the foregoing and other investigations were made g the summer. We have facilities in this and in the ical Class, which are unusually favourable for study research, but at the same time our responsibilities ot diminished by such advantages. We must all er an account of our stewardship. When I mention many facts have yet to be determined in regard to common food-fishes—their development, rate of th, their life-histories and migrations—that we have a to find out as to the best methods of increasing valuable fishes as the cod, the haddock, the sole, and , and of maintaining that increase, it will be ap- nt that such problems are not only of moment to us o the country, and that we cannot begin too soon to pt their solution, as well as to increase our knowe- in regard to many of the lower forms of animal

THE NEW UNIVERSITY OF STRASBURG

THE following account of the new university buildings of Strasburg is taken, with a few abbreviations, from article contributed to our contemporary *La Nature*, M. Charles Grad, who is himself a deputy to the erial Reichsrath from Alsace.

n Monday, October 27th, 1884, the new buildings of University of Strasburg were opened with due for- ities. These buildings form an entire quarter of the and constitute a magnificent series of palaces for the prosecution of science. No city in Europe, not even excepting the great capitals, can show such a rich provision for higher education, or one in which the various parts are so admirably combined. Every branch of study has its own proper and distinct location allotted to it, with laboratories, museums, library, and special appliances. It has been done on the large scale, and most successfully. The Imperial Government and the representatives of the Alsatian population arrived at an understanding, and vied in their efforts to endow the province of Alsace-Lorraine with a school of learning unrivalled in its arrangements and in its wealth of buildings. Even those who were most severely touched by the annexation to Germany, agree that in raising this splendid monument —the new University of Strasburg—the one wish has been to serve the interests of science apart from all sinister or narrow national considerations.

The former Académie of Strasburg, broken up in 1870 by the war, was replaced by the new University by virtue of a decree issued from the Chancelry of the German Empire, under date of December 11th, 1871—the same day on which the additional convention of the treaty of peace was signed at Frankfort. This decree entrusted the organisation of the teaching staff to M. von Roggenbach, formerly Minister of the Grand Duchy of Baden. From

FIG. 1.—University of Strasburg: The Collegiate Palace.

the summer semester of 1872 onwards a body of forty-two professors constituted the staff. They began their work on May 1st of that year, being the three hundred and fifth anniversary of the opening of the Académie, which was founded May 1st, 1567, by the Stattmeister Johann Sturm von Sturmeck. At the present time the new University of Strasburg counts seventy-three ordinary and nineteen extraordinary professors, who during the summer semester of the year 1884, have conducted in the five faculties no fewer than 242 courses of lectures and classes. The work is thus distributed between the five faculties:

Faculty.	Professors.	Classes and Lectures.
Theology	7	26
Law and Political Sciences	12	29
Medicine	26	60
Philosophy	25	77
Natural Sciences & Mathematics	22	50

Side by side with the laboratories and hospitals attached to each special branch of the natural and medical sciences, there exist the seminaries appropriate to the other branches of learning duly equipped for the purpose of initiating the student into the real work of his subject. A fine library of 560,000 volumes, and a reading-room furnished with 371 periodicals, reviews, and journals, are fitted up in the ancient episcopal residence or château, for the use of both pupils and masters. At the beginning of

the] year 1884 the University counted 858 matriculated students, of whom but 266 were from Alsace-Lorraine. We may complete these statistical details by recalling how, since the annexation, the sum devoted to the outfit of the University of Strasburg has amounted to 16,000,000 francs (£640,000), without reckoning the value of the establishments of the ancient Académie, or the cost of the library, which was 1,785,000 francs (£71,400). There is also an annual endowment of 1,067,227 francs [illegible] for the maintenance of the University, and one of 150,000 francs (£6,000) for that of the library, both charged on the Imperial budget, to meet the current necessities, in addition to the income derived from older special endowments.

FIG. 2.—The Collegiate Palace; Salle des Pas-Perdus.

The cuts which illustrate the different establishments of the University, and which convey better than any mere description some faint sense of the scale on which this work has been done, and for which we have to thank the kind attention of M. Schricker, secretary of the Senate of the University, were prepared from photographs taken to accompany a memorial document published at Strasburg in 1884 entitled *Festschrift zur Einweihung der Neubauten der Kaiser-Wilhelms Universität*. The buildings at present finished are spread in two great groups around the civil hospital and in the new quarter of the town now rising between the Promenade des Contades and the Porte des Pêcheurs; the latter being outside the line of fortifications demolished in 1871. It may be remembered that Strasburg now covers within its new fortifications an area thrice as great as that of the old [illegible]

annexation to Germany; and its population was 104,000 at the census of 1880.

It will take you half-an-hour to walk from the medical institutes, grouped around the square of the civil hospital, across the old streets, which still preserve the primitive appearance and the characteristic marks of mediæval German cities, to the new collegiate palace. As you cross from the Kaiserplatz towards the Ill, there rises before you the façade of the collegiate palace, built in imitation of the Vosges (Fig. 1). This is, properly speaking, the only building of the University, the various institutes being so many annexes. The palace is a very fine building, in the style of the Renaissance, with simple lines, standing within a square with fountains and gardens. The plan [illegible]

ed T shape, giving a frontage of 410 feet in length e façade. The two lateral wings and the central per are thrown forward a little and rise slightly above est of the building. A fine external flight of steps into the interior. The basement is of red sand- ; the two stories of grey. Over the five entrance es stand five Corinthian columns supporting a frieze, rmounted by a group of five sculptured figures, con- ably above life-size. Pallas Athene, protectress of science, stands before her throne in a calm and solemn attitude, holding up her torch in her right hand, and lowering a crown in her left. On the two sides of the throne the personifications of philosophy and natural science are each occupied in teaching a young man who reclines at their respective feet. One of these youths endeavours to raise a veil from a sphinx, under the direction of the elder muse, whilst the younger sister, with compass and crystal explains to her scholar a scientific

ems. Under the group is the inscription in Roman s: LITTERIS ET PATRIÆ. In five niches under the ows of the upper floor, and between the five columns, ve bronze busts, representing the five faculties in the ns of Saint Paul, Solon, Aristotle, Hippocrates, and imedes. Two other niches on the right and left of five columns contain female statues personifying sburg and Germany. There are also thirty-six stone es at the angles of the building. As will be seen the plans (Figs. 3 and 4) the central block and each ments and the class rooms in the wings. The seminaries of the faculty of philosophy and the collections of archæology and historical art are placed, along with the aula or great theatre on the higher storey. The plans were drawn by Prof. Warth of Carlsruhe, who also directed the works of construction from 1874 to 1884.

The official rooms of the secretary and of the rector, spacious in proportion, occupy the south wing of the ground floor, along with the senate hall and the music hall; for musical science enters also into the curriculum

Fig. 5.—The Institute of Chemistry.

Fig. 6.—The Institute of Physics.

e wings encloses an internal court. The central court ized, and constitutes an enormous hall, the Salle des Perdus (Fig. 2), 92 feet long, 82 feet wide, and 52½ high. The galleries of the upper floor open upon this which is lighted exclusively from the top. The in- uration ceremony was held in this hall. All official ces are posted here or in the side alleys. In allocating various rooms of the building the architect placed on lower storey the offices of the administrative depart- of the University. In the richly decorated hall for meetings of the senate the ceiling is particularly noticeable. On the left of the entrance in the north wing of the ground floor the corridors lead to the professor's parlour and to the lecture-rooms of the various faculties. These lecture-rooms contain altogether 963 seats, varying in individual rooms according to the varying requirements from 27 to 208 places. With the exception of two, the seminaries for practical studies are placed on the higher floors, so as

to be quiet enough for their purpose. They are open either all day or during certain hours, under the superintendence or direction of the professors, who each have their own private room beside the room allotted to students.

FIG. 7.—The Astronomical Observatory.

These seminaries correspond in their particular line to the laboratories of the faculty of natural science; and they provide for students' collections, appliances and special libraries for each branch of instruction. Placed side by

FIG. 8.—The Institute of Botany.

side along the corridors they are each readily accessible to members of neighbouring seminaries. Starting from the middle of the principal building there are successively the seminaries of the Romanesque languages and of

FIG. 9.—The Institute of Anatomy and Pathology.

English, the philological seminary, the institute of archæology, the German seminary, the seminaries of historical science, of philosophy, of jurisprudence, and of political science. All the northern half of the first floor is devoted to art collections, extending from the seminary of [illegible] science to the aula or great theatre. In the middle of the western façade is the common lecture hall, flanked on one side by the library of the institute of archæology, the other by the rooms of the institute of history. A particular hall is reserved for temporary exhibitions. Then comes the hall of Egyptology and the archæological museum organised with as much taste as science by Michaelis, the professor of archæology. Egyptology and Arabic have each a special professor.

Beside the seminaries and the art collections, the principal floor contains the aula or festival theatre, used

FIG. 10.—The Surgical Clinical Hospital.

for University commemorations. Lit from above the hall occupies the middle of the front façade, and is approached at both ends by the grand staircases. Five open arches separate the aula from an exterior room reserved for the public. The theatre itself is 82 feet long, 47½ feet wide, 33 high. It seats 450 persons, whilst the external room admits of 200 to 300 standing places. The decorations are in plaster, and there is a bust of the Kaiser Wilhelm against the northern wall in white marble.

The heating arrangements—partly hot air, partly hot water—are in the basement, a combined system being used for the class-rooms, hot air alone for the [illegible]

FIG. 11.—The Clinical Hospital for Mental Diseases.

and for the great hall. The ventilation is operated by engines. All the windows are double glazed to prevent too rapid cooling. No scientific appliance has been forgotten which might secure good sanitation. The [illegible] rector's apartments, the staircases, and the Salle des Pas Perdus are richly ornamented in plaster and with painting. The lecture halls and class rooms are more simple and severe as befits their purpose, but for that very reason nothing has been omitted to give them a solid and almost monumental construction. Sandstone relieved with [illegible] prevails in the interior; whilst the floors of the vestibules and corridors are of mosaic and terrazzo.

of the special institutes of chemistry, physics, pharmacy, and astronomy, which are grouped be- e collegiate palace, merit a particular description, as the hospitals of surgery, obstetrics, and ry, and of physiology belonging to the faculty of e, which are grouped around the civil hospital. f these are given in Figs. 5 to 15. Each of these s is independent and separate from the others, d with everything appropriate to its specific pur- In order to enable the professors, who are the s of the special institutes, to follow fully the work

FIG. 12.—The Maternity Hospital.

students and the practice of the laboratory, they ovided with residential apartments in the same gs. To the institute of astronomy is added an mical observatory. This is at the present time d by Dr. Schur, in consequence of the protracted of Prof. Winnecke, who was assistant at the atory of Pulkowa before coming to Strasburg. At titute of botany, Prof. von Bary, whose work on gamic flora is well known, has laid out a new garden, to which a second hothouse is yet to be

To complete the organisation of the University hments there remain to be erected an institute of

y, an institute of zoology, and an institute of ology. The institute of geology, to be directed by denecke, will receive the mineralogical and palæon- al collections, and at the same time will accommo- e work of the geological survey of Alsace-Lorraine. the institute of meteorology, its utility has been y admitted by the provincial government, and its ishment is only a question of time.

ard the sum of 16,000,000 of francs (£640,000) ex- d up to this year on the new University of Strasburg rman Empire has contributed the sum of 3,800,000 , or 4,750,000 francs (£190,000); and of this sum 2,875,000 francs (£115,000) were spent on the collegiate palace. The institute of chemistry alone cost 875,000 francs (£35,000); the institute of physics, 728,750 francs (£29,150); the institute of botany with its garden, 655,000 francs (£26,200); the astronomical observatory, 642,000 francs (£25,600); the institute of anatomy, 1,048,500 francs (£41,740); the surgical clinical hospital, 662,500 frans (£26,500); the institute of physiological chemistry, 400,000 francs (£16,000); the institute of physiology, 337,500 francs (£13,500). It is impossible to give here the details of each institute. Suffice it that each establishment has profited by the latest advances of science, and provides

FIG. 14.—The Institute of Pharmacy.

every means of research to students. Henceforth the institutes annexed to the University of Strasburg will serve as models for the installation of similar buildings. They are not only most complete, but are already sought by students. Thus the institute of chemistry, under the direction of Prof. Fittig, is designed to receive 100 students in its two divisions of organic and inorganic chemistry; and there is not a single vacant place. Further information respecting the various institutes and their organisation can be learned from the *Festschrift*, already alluded to as having been written by M. Schricker to commemorate the opening. As the great library of the country has been

FIG. 15.—The Institute of Physiology.

but temporarily housed in the episcopal château near the Cathedral (in consequence of the fire during the bombardment of 1870) it is intended to remove it to the neighbourhood of the collegial palace of the University. At present, beside the special libraries of the several seminaries, there is only one reading-room (Fig. 3, No. 32) for periodicals and reviews.

Down to the present time the native Alsatians and Lorrainers have not frequented the new university as much as might have been expected in proportion to the needs of the province. Young men still turn towards France to follow their studies for the professions at Paris or at

Nancy. Meantime the recruiting of lawyers and doctors goes on at Strasburg with foreign elements, not without some regret on the part of the native inhabitants. But little by little the force of circumstances is tending to bring the young Alsatians to constitute the University of Strasburg in spite of sentiment. Instead of 69 students, natives of Alsace-Lorraine, registered in 1872, the University registers showed 252 in 1884—a notable increase. As against 5,990 matriculated students at the University of Berlin, 3,399 at Leipzig, 2,276 at Munich, 1,646 at Breslau, 1,452 at Halle, 723 at Heidelberg, 625 at Freiburg, there were to be reckoned but 858 at Strasburg during the summer semester of 1884. No doubt this number will increase rapidly; for in no other centre of the higher education are the means of work so abundantly provided. As to the professorial staff, it includes many celebrities, amongst whom may be named Labaud in the faculty of law; Reuss in the faculty of theology; Brentano, Krapp, and Merkel in political science; Kussmaul, Lucke, and Recklinghausen in the faculty of medicine; Gerland, Michaelis, and Studemond in the faculty of philosophy; Kundt, Benecke, von Bary, and Fittig in the faculty of natural sciences. In selecting these names we do not forget the glory of the former university of the last century, when Strasburg had amongst the number of its celebrities Profs. Blessig, Lauth, Schœpflin, Schweighæuser, Oberlin, worthy predecessors of the Duvernoys, Schimpers, Gerhardts, Pasteurs, Daubrées, Sédillots, Janets, Fustels, Coulanges, Forgels, and Kusses of our time. On August 6th, 1771, Goethe graduated doctor of laws of the University of Strasburg, with a thesis on the respective rights of State and Church. If to-day the new University has as an accessory function that of contributing to the Germanisation of the annexed provinces, it may at least be said that the staff of professors of the older university of last century had rallied to French politics in the most open manner. Witness the address to King Louis XV. dated October 6th, 1744:—"Sire, the most faithful of the universities in your kingdom offers to your Majesty its homage and its good wishes. Penetrated with joy at the convalescence and at the arrival of its august monarch, it to-day, Sire, finds united in you the father of the people, the protector of the muses, the liberator of Alsace, and the hero. It is to these glorifications of your rare virtues, great king, that we consecrate our work, happy if our words may correspond to the effusion of our hearts, and merit the continuation of the good graces of the most puissant and most beloved of the sovereigns of Europe."

Formerly the Académie of Strasburg took up the special task of serving as an intermediary between France and Germany for the propagation of ideas and of the scientific movement. More richly endowed, the new University, applying its greater powers to the development of the human mind, will recognise that the representatives of the people of Alsace-Lorraine have wished to promote its efforts in the largest and most generous manner in the higher interests of science. Science ought to contribute to the union of the people; it has no exclusive national character, and it serves to advance the reign of peace in the world by assuring to us greater prosperity and greater light, whilst developing in us all the love of our own country.

NOTES

THE Royal Medals of the Royal Geographical Society will this year be awarded to Mr. Joseph Thomson and Mr. H. E. O'Neill—to the former for his well-known work in Africa, and to the latter for his thirteen journeys of exploration along the coast and in the interior of Mozambique. The Murchison Grant for 1885 will be awarded to the Pandit Kreshna for his four explorations made while attached to the Survey of India, and especially for his extensive and important journey in the interior of Tibet. The Back Gold Medal of W. O. Hodkinson for his Australian explorations, and the Cuthbert Peek Grant to Mr. J. T. Last for his services in ethnological researches in the Southern Masai, Ugogo, and other neighbouring countries. The following will be the Honorary Corresponding Members:—Chief Justice Daly, President of the Geographical Society of New York; M. Elisée Reclus, the eminent geographer; and Herr Moritz von Déchy, the distinguished Austrian explorer of the Sikkim Himalaya, the Caucasus, and other regions.

IT is announced that the next meeting of the American Association for the Advancement of Science will be held on August 26 and following days, at Ann Arbor, Mich.

AT the annual conference of the French Astronomical Society, which met on the 8th inst. in Paris, MM. Faye, Mouchez, and Darboux, were appointed president and vice-presidents respectively of the section for the mathematical and physical sciences, and MM. de Quatrefages, Milne-Edwards, and Marey occupy the same offices in the section for geographical and natural sciences.

M. HERVÉ-MANGON, the new French Minister of Agriculture, is a Member of the Academy of Sciences in the Section of Rural Economy and a Professor of Agronomy in the Conservatoire des Arts et Métiers. He was for some time a Library of the latter establishment, but resigned in order to accept a seat in the French Lower House. He married the daughter of the late M. Dumas.

THE next Ordinary General Meeting of the Institution of Mechanical Engineers will be held on Thursday, April 30, and Friday, May 1, at 25, Great George Street, Westminster. The chair will be taken by the President, Mr. [illegible], at half-past three o'clock p.m. on Thursday, and at half-past seven o'clock p.m. on Friday. The following papers will be read and discussed, as far as time will admit:—Description of the Hiram automatic machine-gun, by Mr. Hiram S. Maxim, of London; Abstract of results of experiments on riveted joints, with applications to practical work, by Prof. Alexander [illegible] Kennedy, of London (including the latest experiments described in Prof. Kennedy's Report, issued to the members of the Institution); Description of the Tripier Spherical Eccentric, by M. [illegible] Poillon, of Paris; Description of a blooming and rail mill top roll at the Ebbw Vale Works, by Mr. Calvert [illegible], of Ebbw Vale.

THE Annual Report of the French Central Meteorological Department states that the weather forecasts last year were found in 90 cases out of every 100, the percentage having steadily risen from 81 in 1881 to 83 in 1882 and to 87 in 1883. Out of 1,[illegible] alarm signals sent to the ports, 128 were fully verified, 1,[illegible] fairly correct, 37 incorrect, and only two gales were not foreseen. This year the gale of January 11 was foretold, as was that of March 22, which did such damage at Charleroi, but not predicted. It took place in exceptional circumstances, and was of short duration.

DURING the second half of last year several communications appeared in NATURE relating to the nests from which the Chinese birds'-nest soup is made. Mr. Pryer, after an account of his visits to the Gomantu Caves in Perak, Borneo, where the nests are chiefly found, imitated the swallows, and now addressed a long communication to the editor of a Chinese English journal published in Japan, the main points of which appear to be as follows:—(1) Owing to a misapprehension, Mr. Pryer was represented as saying that the Kun-ti-lan of the caves constructed the nests as well as the swallow. The latter has nothing to do with the nests. (2) Mr. Lister, as first published in NATURE (November 27, 1884), speaks of "masses of blood, from the efforts of the birds to produce [illegible]. In

ver thinks that the patches of brown-red on the nests may be e to blood from the hands of the gatherers, or to the betel- ce which they constantly expectorate, but not to the bird's od. (3) The birds do not eat algæ; they are purely insectivor- s. (4) Mr. Green says (NATURE, December 11) that a chemi- and microscopical examination of the nests suggests that they made from the saliva of the bird. This Mr. Pryer regards a physical impossibility, for the bird could not secrete in a days a mass of saliva more than equal, when dried, to the ire bulk of its own body, and then do this nine consecutive es a year. He thinks that, undoubtedly, some saliva is used the birds, the algæ (which Mr. Pryer incorrectly called ungoid growth" in his first account) being used in same way as a Japanese swallow (*Cecropis japonica*) uses d. This bird gathers pellets of mud and works them up its mouth, forming a strong cement, constructing a large tle-shaped nest, sometimes nearly two feet long; and exactly the *Cecropis japonica* uses mud, so the Bornean *Collocalia iphaga* uses algæ, producing thereby the delicate structure own as edible bird's nest. Besides, Mr. Pryer states that nest examined by Mr. Green was probably not genuine, as substance is very easily imitated, and the high price would nulate adulteration. (5) His previous theory that the dis- tion between white and black nests is due to the brown side of the algæ being used for the latter, he now renounces. e birds can only use the inside, and black nests are simply ite nests grown old and repaired frequently. The difference not due to any difference in the site or in the kind of bird. is is the writer's present theory. Owing to some accident (a ive printer's mishap possibly), portions of Mr. Pryer's paper not quite coherent and connected, and some of the words phrases are misplaced with that ingenious absurdity so racteristic of printers' blunders; but we believe we have en the substance of the communication here.

THE sixteenth annual report of the American Museum of tural History has just been published. Besides various addi- ns to the collections during the year—the principal being 44 imens of North American birds, 29 specimens of North erican mammals, and 20 monkeys—the trustees report a step reat importance taken in creating a section in the museum ed "The Department of Public Instruction." The Legis- re of the State of New York having appropriated a sum to ble the curators of the museum to give free lectures, illustrated ts collections, to the teachers of common and normal schools ughout the State, the trustees have accepted the duty, and e arranged for a series of lectures extending over four years, ity in each year, all to be richly illustrated with original s and drawings specially prepared for the course. The iculum for the first course 1884-85 includes human anatomy physiology, forestry, building and ornamental stones, and nimal kingdom.

R. J. A. ALLEN, who for many years has had charge of mals and birds at the Museum of Comparative Zoology at bridge, has, *Science* states, accepted the curatorship of malogy and ornithology in the American Museum of Natural ory in New York, where he will enter upon his new duties t May 1.

HE American Government have sent 30,000 land-locked on to the National Fish Culture Association, which arrived aturday in excellent condition. In this country the hybrid- on of the various species of Salmonidæ is extensively prose- d; and it is proposed to try the experiment of cross-breeding and-locked salmon with the brook trout or char, thus pro- ng the culture of a better class of fish than the trout which abound in our rivers.

R. H. J. JOHNSTON-LAVIS, of Naples, announces the ap- ching publication of a "Monograph of the Earthquakes of Ischia," a memoir dealing with the seismic disturbances in that island from remotest to recent times, with special observations on those of 1881 and 1883, by himself, with some calculations by Rev. Prof. Samuel Haughton, M.D., F.R.S., F.G.S., &c. The work will be published by subscription, and intending sub- scribers should communicate with the author, 7, Chiatamone, Naples.

A SHARP shock of earthquake was felt in Rome on the night of the 9th inst. Bells were set ringing, and many persons were momentarily alarmed by the movement, but that was the extent of its effect. Prof. Stefano Michele de Rossi has communicated the following report to the Press:—"At 2.44 a.m. a distinct shock of earthquake aroused a great part of the population of Rome. From the observations obtained it belonged to the sixth degree of the conventional scale of 10 degrees for intensity. It undulated from south-west to north-east, and then from north- west to south-east. The full duration was about 10 seconds, of which four were occupied by the second phase of the pheno- menon. A telegram from Avezzano states that the shock was very strong there in the direction of north to south. No damage done." Telegrams received later from Frosinone report that a shock was felt there at the same time with sufficient force to create general alarm among the population.

THERE has been a renewal of earthquake shocks in the pro- vinces of Granada and Malaga. Early on the morning of the 11th oscillations of more or less violence are reported from Velez Malaga, Antequera, Motril, and the city of Granada itself and some surrounding villages. So far as is known there has been no loss of life or serious damage, but the panic at some places is described as intense, and the inhabitants, refusing to return to their houses, remain in the open country.

SEVERAL shocks of earthquake were felt at Geneva on the 13th.

THE most recent contribution to the much-discussed question of the origin of the mound-builders of the United States is a pamphlet by Mr. C. E. Putnam, issued by the Academy of Natural Sciences of Davenport, Iowa. The Bureau of Ethnology connected with the Smithsonian Institute champions the theory that the race which constructed these mounds may be traced to the ancestors of the present American Indians, while another school of archæologists holds that the mound-builders were more advanced in civilisation than the American Indians, and have endeavoured to trace them to a Mexican origin, or to some common ancestry. This being the broad question at issue, the Davenport Academy, which appears to have adopted no theory on the subject, became possessors by donation of three inscribed tablets and two elephant pipes, *i.e.* pipes with the figure of an elephant carved on them, which are stated to have been found in Iowa. In the words of Mr. Putnam, "if their authenticity is established, then archæologists will find in them strong corro- borative evidence that man and the mastodon were contemporary on the American continent, and the mound-builders were a race anterior to the ancestors of the present American Indians, and of higher type and more advanced civilisation." But doubts have been cast on the authenticity of these curious relics by the Bureau of Ethnology, and the Davenport Academy has taken the matter up with some warmth. Mr. Putnam's pamphlet is the Academy's reply, and is a vigorous defence of the genuineness of the elephant pipes and inscribed tablets. It describes in detail the circumstances under which they were discovered, the witnesses present, &c., and lays especial stress on the fact that the two pipes were dug up at different times and places, by independent persons, one, at least, of whom had no notion of the value of the object. The whole subject is one of extraordinary interest, and Mr. Putnam's statement, vouched as it is by a formal resolution of the Davenport Academy, must play an important part in any

subsequent discussion as to the value to be attached to these remains, which, if authentic, are acknowledged to have much influence on the final settlement of the question as to who the mound-builders were.

THE use of artificial teeth is not so modern as is generally believed. *Cosmos* states that in the museum of Corneto, on the coast of Italy, there are two curious specimens of artificial teeth found in Etruscan tombs probably dating to four or five centuries before our era. These graves contained the bodies of two young girls. On the jaw of one is still to be seen two incisors fixed to their neighbours by small gold rings; in the other the rings remained, but the artificial teeth had fallen out. The teeth, carefully cut, had evidently been taken from the mouth of some large animal. The dentist's art amongst the ancients was not confined to drawing teeth, and replacing them by artificial ones, for natural teeth have been found which have evidently been treated in various ways. That this curious fact has escaped notice so long, is due to the rarity of Etruscan skeletons, the Etruscans employing cremation generally, and also to the circumstance that modern inquirers are more interested in objects of Etruscan art and industry than in the remains of their ancient owners.

WE have received from the Rev. H. H. Higgins the reprint of a paper read by him before the Literary and Philosophical Society of Liverpool on Museums of Natural History. The writer discusses the subject under four heads, to which a fifth, on the British Museum of Natural History, is added. These are Museum visitors' desiderata, arrangements and appliances. Judging from the attendance at the Liverpool Museum, he calculates that a large majority (about 780 in 1000) of the visitors are those who are not conscious of any purpose beyond a wish to see the Museum, but who fix their attention with more or less intelligence on the objects displayed. The students would number about ten to twenty, and loungers, including children, 200 in the thousand. The first desideratum in a public museum is a better treatment of the specimens which they already possess. The Museum, Mr. Higgins thinks, is a rare one, in which a donation of 100*l.* could *best* be spent in the purchase of fresh specimens; in almost all instances it could be better spent in making the order more intelligible and more instructive, and much of this good work might be done without spending any money. The sections on arrangements and appliances contain many interesting suggestions on these important elements in the success of a museum. A *stammbaum*, or phylogenetic scheme of the pedigree of animals and vegetables, by Prof. Herdman, of University College, Liverpool, is added to Mr. Higgins's paper.

WE have received Dr. Howden's presidential address to the Montrose Scientific and Field Club, on the "Aims of a Naturalists' Field Club," which contains much useful advice as to the methods in which the members of such societies should regulate their studies and researches. What has already been done in local natural history in the vicinity of Montrose and suggestions as to what still lies ready at hand to be done, are described in the concluding portion of the address.

Timber, a weekly journal devoted to the timber and kindred interests, is the title of a new journal, the first number of which appeared on February 28. A large portion of this periodical is occupied with trade announcements and records of sales, with a sprinkling of short articles and paragraphs on subjects connected with the uses of timber or the timber supply. The paper is intended for circulation among, and as the representative of, the numerous trades who work in timber, and does not profess to be anything else.

THE experiments in Paris by the Triboulet system of photographing all the country seen from a captive balloon by opening the valve of a panoramic object-glass with a [illegible] the ground has succeeded wonderfully well. As the [illegible] remain on the ground a very small balloon [illegible] the photographic apparatus. The impressions [illegible] films can be inspected with a microscope, and are [illegible] military purposes.

THE additions to the Zoological Society's Gardens [illegible] past week include a Pig-tailed Monkey (*Macaca nemestrina*) from Java, presented by Mrs. Urquhart; a Chinese [illegible] (*Acridotheres cristatellus*) from China, presented by Mr. [illegible] Rowler; a Galeated Curassow (*Pauxis galeata* ♀) from [illegible] aela, presented by Mr. G. A. Crawley; a Chilian [illegible] (*Geranoaetus melanoleucus*) from Chili, presented by [illegible] J. Jones; a Carrion Crow (*Corvus corone*), British, presented [illegible] Mr. A. Browning Priestley; a Smooth Snake (*Coronella*) from Hampshire, presented by Mr. W. H. B. Fair; a [illegible] Wild Ass, or Kiang (*Equus hemionus* ♀) from Thibet [illegible] Sonnerat's Jungle Fowls (*Gallus sonnerati* ♂ ♀) from [illegible] Southern India, deposited; a Mandarin Duck (*Aix galericulata* ♂) from China, a Dark Green Snake (*Zamenis gemonensis*) [illegible] South European, purchased; two Rendall's Guinea Fowls (*Numida rendalli*) from East Africa, received in exchange; a Gigantic Salamander (*Megalobatrachus gigas*) from China; two Bull Frogs (*Rana catesbiana*) from North America [illegible] on approval; a White-fronted Lemur (*Lemur albifrons*) [illegible] in the Gardens.

GEOGRAPHICAL NOTES

MR. WADA, of the Japanese Legation in Berlin, [illegible] before the Geographical Society there certain maps [illegible] the Geological Survey of Japan, which represent the [illegible] to the present of that establishment. It was founded in [illegible] was organised by Dr. Naumann, a German geologist, [illegible] sists of topographical, geological, and agronomical [illegible] of a technical and chemical laboratory. The maps [illegible] the department for the Geological Congress of Berlin [illegible] were:—(1) An oroplastic map, on a scale of 1/[illegible], [illegible] the general position and form of the Japanese [illegible] coasts, ranges of mountains, as well as the depths of [illegible] off the coast. (2) A magnetic map. During the [illegible] topographical survey magnetic variations were [illegible] the help of a portable magnetometer. Magnetic [illegible] are of extraordinary interest in Japan. The [illegible] the variations are frequently very different in [illegible] rous volcanoes causing great irregularity. (3) A [illegible] constructed from the preliminary surveys of Dr. [illegible] native geologists. This is based on a topographical [illegible] is not reliable in detail; but it shows the knowledge [illegible] far of the geological structure of Japan. From this [illegible] that all the formations are met with in that country, [illegible] zoic being universal. Next to these in extent comes [illegible] complete report on this subject is to be made by the [illegible] the Survey to the Congress. The topographical [illegible] now for about four years, and the area surveyed is [illegible] eighty geographical miles square. The completion of [illegible] for the whole country will take another eight years. [illegible] tailed geological survey has reached about the same [illegible] the topographical survey, but none of the sheets [illegible] have yet been published, although they exist in manuscript [illegible] to the 38th parallel, with the exception of Yezo. [illegible] well as the text, appear in Japanese and English. [illegible] vey publishes also annual reports, eight of which [illegible] appeared, but only in Japanese. Another report [illegible] for the Congress, in one of the volumes of which the [illegible] tinguished by colours. An important portion of the [illegible] the Survey is the study of soils. According to Mr. [illegible] volcanic tufa, consisting for the most part of [illegible] cates, forms a large part of the numerous [illegible] the foot of the mountains. An accurate knowledge [illegible] be of much value to agriculture. Japanese soil is [illegible] stated to be poor in chalk. This subject will also be [illegible] by the head of the Agronomical Section before the [illegible] Congress.

e last *Bulletin de la Société de Géographie* (1er Trimestre, contains a paper by M. de Mailly-Chalon on a journey anchuria. With two countrymen he left Peking for New-ng, and thence passing to the east of Moukden, through to Ninguta, where the party turned to the south-east the Tiumen, towards the ocean, and reached Vladivostock. journey the whole way was along the Corean frontier. ng Vladivostock the travellers crossed Siberia to Tomsk, which they went to Samarkand. From this point the story e journey is taken up by another member of the party, Benoist-Méchin, whose paper on the journey across stan succeeds M. Mailly-Chalon's. This journey led them Samarkand through Karshi, to Bokhara, thence to the -Darya at Charjui. They followed the river then down tro-Alexandrovsk, whence they deviated to Khiva. From tter town they retraced their steps up the river, and from an-Chin started across the Kara-Kum to Merv, and so to ds and Persian territory at Meshed. The journey, here y indicated, lasted two years, *i.e.* from the departure from for Peking to the arrival in Teheran. M. Rabot writes ordenskjold's expedition to Greenland, the paper being illed from the Professor's reports to Mr. Oscar Dickson, shed in the *Journal* of the Swedish Society of Anthropo- and Geography. M. Charles Huber brings to an end his journeys in Central Arabia, between 1878 and 1882, to h we have adverted in noticing previous numbers of the *elin*.

r the meeting of the Paris Geographical Society on the 7th M. Giraud was received with great distinction, and detailed ecent travels in Africa. The explorer has received the medal of the Society and the Cross of the Legion of our.

STRONOMICAL PHENOMENA FOR THE WEEK, 1885, APRIL 19-25

or the reckoning of time the civil day, commencing at nwich mean midnight, counting the hours on to 24, is here loyed.)

At Greenwich on April 19

ON A REMARKABLE PHENOMENON OF CRYSTALLINE REFLECTION[1]

Introduction.

IN a letter to me, dated March 29, 1854, the late Dr. W. Bird Herapath enclosed for me some iridescent crystals of chlorate of potash, which he thought were worth my examination. He noticed the intense brilliancy of the colour of the reflected light, the change of tint with the angle of incidence, and the apparent absence of polarisation in the colour seen by reflection.

The crystals were thin and fragile, and rather small. I did not see how the colour was produced, but I took for granted that it must be by some internal reflection, or possibly oblique refraction, at the surfaces of the crystalline plates that the light was polarised and analysed, being modified between polarisation and analysation by passage across the crystalline plate, the normal to which I supposed must be sufficiently near to one of the optic axes to allow colours to be shown, which would require no great proximity, as the plates were very thin. To make out precisely how the colours were produced seemed to promise a very troublesome investigation on account of the thinness and smallness of the crystals; and, supposing that the issue of the investigation would be merely to show in what precise way the phenomenon was brought about by the operation of well-known causes, I did not feel disposed to engage in it, and so the matter dropped.

But more than a year ago Prof. E. J. Mills, F.R.S., was so good as to send me a fine collection of splendidly coloured crystals of the salt of considerable size, several of the plates having an area of a square inch or more, and all of them being thick enough to handle without difficulty. In the course of his letter mentioning the despatch of the crystals, Prof. Mills writes: "They [the coloured crystals] are, I am told, very pure chemically, containing at most 0·1 per cent. foreign matter. They are rarely observed—one or two perhaps now and then in a large crystallisation . . . I have several times noticed that small potassic chlorate crystals, when rapidly forming from a strong solution, show what I suppose to be interference colours; but the fully formed crystals do not show them."

Some time later I was put into communication with Mr. Stanford, of the North British Chemical Works, Glasgow, from which establishment the crystals sent me by Prof. Mills had come. Mr. Stanford obligingly sent me a further supply of these interesting crystals, and was so kind as to offer to try any experiment that I might suggest as to their formation.

On viewing through a direct-vision spectroscope the colours of the crystals which I had just received from Prof. Mills, the first glance at the spectrum showed me that there must be something very strange and unusual about the phenomenon, and determined me to endeavour to make out the cause of the production of these colours. The result of my examination is described in the present paper.

Section I.—*Preliminary Physical Examination.*—1. It will be necessary to premise that chlorate of potash belongs to the oblique system of crystallisation. The fundamental form may be taken as an oblique prism on a rhombic base, the plane bisecting the obtuse dihedral angle of the prism being the plane of symmetry. Rammelsberg denotes the sides of the prism by P, and the base by C, and gives for the inclinations of the faces PP = 104° 22′ and CP = 105° 35′. The face C, which is perpendicular to the plane of symmetry, is so placed as to bring three obtuse plane angles together at two opposite corners of the parallelepiped. The salt usually forms flat, rhombic or hexagonal plates parallel to the C plane, the edges of the rhombus being parallel to the intersections of the P faces by the C plane, and the hexagons being formed from the rhombic plates by truncating the acute angles by faces parallel to the intersection of the C plane by the plane of symmetry.

The plane angles of the rhombic plates, calculated from the numbers given by Rammelsberg, are 100° 56′ and 79° 4′, while the hexagonal plates present end-angles of 100° 56′ and four side-angles of 129° 32′. These angles are sufficiently different to allow in most cases the principal plane of a plate, or even of a fragment of a plate, to be determined at once by inspection. But in any case of doubt it may readily be found without breaking the crystal by examining it in polarised light. There are

[1] Paper read at the Royal Society on March 19 by Prof. G. G. Stokes, M.A., Sec. R.S., Lucasian Professor of Mathematics in the University of Cambridge.

good cleavages parallel to the two P planes and to the C plane. The crystals are very commonly twinned, the twin plane being C.

2. If one of the brilliantly coloured crystals be examined by reflection, and turned around in its own plane, without altering the angle of incidence, the colour disappears twice in a complete revolution. The vanishing positions are those in which the plane of incidence is the plane of symmetry. The colour is perhaps most vivid in a perpendicular plane; but for a very considerable change of azimuth from the perpendicular plane there is little variation in the intensity of the colour. There is no perceptible change of tint, but on approaching the plane of symmetry the colour gets more and more drowned in the white light reflected from the surface.

3. If instead of altering the azimuth of the plane of incidence a plane be chosen which gives vivid colour, and the angle of incidence be altered, the colour changes very materially. If we begin with a small angle the colour begins to appear while the angle of incidence is still quite moderate. What the initial colour is, varies from one crystal to another. As we increase the angle of incidence the colour becomes vivid, at the same time changing, and as we continue to increase the angle the change of colour goes on. The change is always in the order of increasing refrangibility; for example, from red through green to blue. Not unfrequently, however, the initial tint may be green or blue, and on approaching a grazing incidence we may get red or even yellow mixed with the blue, as if a second order of colours were commencing.

4. The colours are not in any way due to absorption; the transmitted light is strictly complementary to the reflected, and whatever is missing in the reflected is found in the transmitted. As in the case of Newton's rings, the reflected tints are much more vivid than the transmitted, though, as will presently appear, for a very different reason.

5. As Dr. Herapath remarked to me long ago, the coloured light is not polarised. It is produced indifferently whether the incident light be common light or light polarised in any plane, and is seen whether the reflected light be viewed directly or through a Nicol's prism turned in any way. The only difference appears to be that if the incident light be polarised, or the reflected light analysed, so as to furnish or retain light polarised perpendicularly to the plane of incidence, the white light reflected from the surface, which to a certain extent masks the coloured light, is more or less got rid of.

6. The character of the spectrum of the reflected light is most remarkable, and was wholly unexpected. A direct-vision hand spectroscope was used in the observations, and the crystal was generally examined in a direction roughly perpendicular to the plane of symmetry; but it is shown well through a wide range of azimuth of the plane of incidence. No two crystals, we may say, are alike as to the spectrum which they show, but there are certain features common to all. The remarkable feature is that there is a pretty narrow band, or it may be a limited portion of the spectrum, but still in general of no great extent, where the light suffers total or all but total reflection. As the angle of incidence is increased, these bands move rapidly in the direction of increasing refrangibility, at the same time increasing in width. The character of the spectrum gradually changes as the angle of incidence is increased; for example, a single band may divide into two or three bands.

The bands are most sharply defined at a moderate angle of incidence. When the angle of incidence is considerably increased, the bands usually get somewhat vague, at least towards the edges.

7. The commonest kind of spectrum, especially in crystals prepared on a small scale, which will be mentioned presently, is one showing only a single bright band; and I will describe at greater length the phenomena presented in this case.

When the angle of incidence is very small, the light reflected from the reflecting surfaces of the crystal shows only a continuous spectrum. As the angle of incidence is increased, while it is still quite moderate a very narrow bright band shows itself in some part of the spectrum. The particular part varies from one crystal to another; it may be anywhere from the extreme red to the extreme violet. It stands out by its greatly superior brightness on the general ground of the continuous spectrum, and when it is fully formed the reflection over the greater part of it appears to be total. The appearance recalls that of a bright band such as the green band seen when a calcium salt, or the orange band seen when a strontium salt, is put into a Bunsen flame. The bright band is frequently accompanied [illegible] left by maxima and minima of illumination, [illegible] altogether subordinate importance as regards their [illegible] Sometimes these seem to be absent, but I cannot [illegible] they are an essential feature of the phenomena, which [illegible] times fail to be seen because the structure on which it [illegible] depend is not quite regularly formed, or whether, on the [illegible] hand, they are something depending on a different [illegible]

Disregarding these altogether subordinate bands, [illegible] account of the mean illumination, it seems as if the [illegible] of the spectrum for a little way right and left of the [illegible] were somewhat less than that at a greater distance.

When the main band occurs at either of the [illegible] spectrum, it is visible, by its superior brightness, [illegible] which, as regards the continuous spectrum, is [illegible] seen, and thus it appears separated from the continuous [illegible] by a dark interval.

When the angle of incidence is increased, the band [illegible] the direction of increasing refrangibility, and at the same [illegible] increases rapidly in breadth. The increase of breadth [illegible] rapid to be accounted for merely as the result of a [illegible] of separation of the colours, which in a diffraction [illegible] would be separated approximately according to the [illegible] reciprocal of the wave-length, while in bands [illegible] direct interference the phase of illumination would [illegible] according to the wave-length.

8. The transmitted light being complementary to [illegible] we have a dark band in the transmitted answering [illegible] band in the reflected. In those crystals in which the [illegible] best formed, it appears as a narrow black band [illegible] light. When the band first appears as we recede [illegible] normal incidence it is extremely narrow, but it rapidly [illegible] in breadth as the angle of incidence is increased.

9. Some of the general features of the phenomena [illegible] prettily shown in the following experiment:—

Choosing a crystal in which the bright band in [illegible] light began to appear, as the incidence was increased, [illegible] red side of the line D, so that on continuing to increase [illegible] incidence it passed through the place of the line D. [illegible] had become of any great width, I viewed through the [illegible] sheet of white paper illuminated by a soda flame. A dark [illegible] was seen on the paper, which was circular, or nearly so, [illegible] interrupted in two places at opposite extremities of a [illegible] namely, the places where the ring was cut by the [illegible] symmetry. The light of the refrangibility of D was [illegible] excluded from the greater part of the ring due to [illegible] nearly black, though slightly bluish, as it was illuminated [illegible] feeble radiation from the flame belonging to refrangibilities [illegible] than those of the immediate neighbourhood of D. [illegible] of the two halves of the ring became feeble as they approached [illegible] the plane of symmetry. A subordinate comparatively bright [illegible] lay in this crystal immediately outside the main one.

10. Suspecting that the production of colour was in some way connected with twinning, I examined the cleavage surfaces of the crystals which happened to have been broken. I found that the bright reflection given by the cleavage surface was interrupted by a line, much finer than a hair, running parallel to the C faces, which could be easily seen with a [illegible] lens, if not with the naked eye. This line was [illegible] illuminated bright surface exposed by cleavage, a [illegible] I suppose illuminated by a source of light not too [illegible] a lamp, or a window at some distance. The plane of [illegible] being supposed normal to the intersection of the cleavage [illegible] by the C faces, on turning the crystal in a proper direction [illegible] a normal to the plane of incidence, the light seemed to be [illegible] flected from the cleavage surface, and after turning [illegible] certain angle, the narrow line which previously had [illegible] was seen to glisten, indicating the existence of a [illegible] surface, though it was much too narrow to get a [illegible] from off it. The direction of rotation required to [illegible] fine line glisten was what it ought to be on the supposition [illegible] the fine line was the cleavage face of an extremely [illegible] stratum.

11. On examining the fine line under the microscope, it was found to be of different thicknesses in different crystals, but in those crystals which showed colour it did not vary perceptibly. On putting a little lycopodium on the cleavage face [illegible] by the fine line, it was seen that in those crystals which showed colour the breadth of the twin stratum varied from a little [illegible] to a little less than the breadth of a spore. The [illegible]

ingly ranged somewhere about the thousandth of an inch, eing the diameter of the spores. The stratum was visibly r in those crystals which showed their bright band in the an in those which showed it in the blue.

That the thin twin stratum was in fact the seat of the admitted of being proved by a very simple experiment. sufficient to hold a needle, or the blade of a penknife (I ppose the latter), close to or touching the surface of the while it was illuminated by light coming approximately direction, suppose from a lamp, or from a window a little f, and to examine the shadows with a watchmaker's lens. ght reflected from the crystal comes partly from the upper ; partly from the twin stratum, partly from the under ; which, however, may be too irregular to give a good ion. The twin stratum is much too thin to allow of ting the light reflected from its two surfaces in an obser- like the present, and it must therefore be spoken of as a reflecting surface. Corresponding to the three reflecting es are three shadows, where the incident light is cut off: m the upper surface, (2) from the twin stratum, (3) from nder surface. By examining these shadows in different ls and under varied conditions, it is shown beyond doubt e coloured reflection comes from the twin stratum.

conclusion was confirmed by observations made with sun- but the simple method of shadows is quite as good, and y itself perfectly satisfactory.

Another useful method of observation, not so very simple as t, is the following. A slit, suppose horizontal, not very , is placed in front of the flame of a lamp at some ss, and an image of the slit is formed by a suitable lens, as the compound achromatic objective of an opera-glass. rystal is placed so as to receive in focus the image of the sing inclined at a suitable angle, usually in a plane per- cular to the plane of symmetry. The eye is held in a on to catch the reflected light, and the images formed by fferent reflections are viewed through a watchmaker's

If the slit be not too broad, the images formed by ion from the upper surface, from the twin stratum, and he under surface are seen distinct from each other, so that he reflected from the twin stratum may be studied apart hat reflected from the upper and under surfaces.

his mode of observation it can readily be seen, by turning rystal in its own plane, and noticing the middle image, is that reflected from the twin stratum, how very small a on out of the position in which the plane of incidence had the plane of symmetry suffices to re-introduce the coloured which had vanished in that critical position, which appears a position not merely of absence of colour, but of absence ht altogether; at least if there be any it is too feeble to be n this mode of observation, though from theoretical con- tions we should conclude that there must be a very reflected light, polarised perpendicularly to the plane of nce.

On allowing a strong solution of chlorate of potash in ater to crystallize rapidly, in which case excessively thin es are formed in the bosom of the liquid, I noticed the play ours by reflection mentioned by Professor Mills as belong- the crystals in general at an early stage of their growth. however, proved to be quite a different and no doubt a simpler phenomenon. The difference was shown by the ration of the light, and above all by the character of the ur of the light so reflected, which resembled ordinary s of interference, and did not present the remarkable cter of the spectra of the peculiar crystals.

When, however, the whole was left to itself for a day or mong the mass of usually colourless crystals a few were here and there which showed brilliant colours. These s were commonly far more brilliant than those of the ls mentioned in the preceding paragraph, and they showed rfection the distinctive character of the spectrum of the lar crystals. It would have been very troublesome, if ble at all, to examine the twinning of such thin and tender de as those thus obtained by working on a small scale; but character of the spectrum, which is perhaps the most rkable feature of the phenomenon, as well as the depend- of the colour on the orientation, may be examined very and thus any one can study *these* features of the phenom- though he may not have access to such fine coloured ls as those sent me by Professor Mills.

A certain amount of disturbance during the early stages of crystallisation, whether from natural currents of convection or from purposely stirring the solution, somewhat gently so as not to break the crystals, seems favourable to the production of the peculiar crystals. When the salt crystallised slowly from a quiet solution I did not obtain them.

17. As it is easy in this way, by picking out the peculiar crystals from several crystallisations, to obtain a good number of them, the observer may satisfy himself as to the most usual character of the spectrum. It is best studied at a moderate incidence, as it is sharper than when the incidence is considerable.

18. The number of coloured crystals obtained by crystallisations on a small scale, though very small, it is true, compared with the number of colourless ones, was still so much larger than Prof. Mills's description of the rarity of the crystals had led me to expect, that I at one time doubted whether the simply twinned crystals which are so very common, if taken at a period of their growth when one component is still very thin, and of suitable thickness, might not possibly show the phenomenon, though the thin twin was in contact on one face only with the brother twin, the other face being in the mother-liquor or in air. The circumstances of reflection and transmission at the first surface of the twin plate must be very different according as it is in contact with the brother crystal, or else with the mother-liquor, or air, or some other fluid; and yet the peculiar spectrum was shown all the same whether the crystal was in air, or immersed in the mother-liquor, or in rock oil. However, to make sure of the matter I took a simply twinned crystal, and ground it at a slight inclination to the C face till the twin plane was partly ground away, thus leaving a very slender twin wedge forming part of the compound crystal, and polished the ground surface. On examining the reflected light with a lens, no colour was seen about the edge of the wedge, where the thickness of the wedge tapered away to nothing; and that, although the bands seen near the edge in polarised light, which was subsequently analysed, showed that had colours been producible in this way, as they are by a thin twin stratum, they would not have been too narrow to escape observation.

In another experiment a simply twinned crystal was hollowed out till the twin plane was nearly reached. The hollowing was then continued with the wetted finger, so as to leave a concave smooth surface, the crystal being examined at short intervals in polarised light as the work went on, so as to know when the twin plane was pierced. But though in this case the twin plane formed a secant plane, nearly a tangent plane, to the worked surface, and near the section the twin portion of the crystal must have been very thin for a breadth by no means infinitesimal, as was shown by examination in polarised light, yet no colours were seen by reflection. I conclude therefore that the production of these colours requires the twin stratum to be in contact on *both* its faces with the brother crystal.

19. The fact that a single bright band is what most usually presents itself in the spectrum of the reflected light, though sometimes two or three such bands at regular intervals may be seen, seems to warrant us to regard that as the kind of spectrum belonging to the simplest form of twin stratum, namely, one in which there are just the two twin surfaces near together. The more complicated spectra seem to point to a compound interference, and to be referable to the existence of more than two twin planes very near together; and in fact in some of the crystals which showed the more complicated spectra, and which were broken across, I was able to make out under the microscope the existence of a system of more than two twin planes close together. Restricting ourselves to what may be regarded as the normal case, we have then to inquire in what way the existence of two twin planes near together can account for the peculiar character of the spectrum of the reflected or transmitted light.

Section II.—*Of the Proximate Cause of the Phenomenon.*—20. Though I am not at present prepared to give a complete explanation of the very curious phenomenon I have described, I have thought it advisable to bring the subject before the Society, that the attention of others may be directed to it.

That the seat of the coloration is in a thin twin stratum, admits I think of no doubt whatsoever. A single twin plane does not show anything of the kind.

For the production of the colour the stratum must be neither too thick nor too thin. Twin strata a good deal thicker than those that show colour are common enough; and among the crystals sent to me I have found some twin strata which were a good deal thinner, in which case the crystal showed no colour.

The more complicated spectra which are frequently observed seem referable to the existence of more than two twin planes in close proximity. There is no reason to think that the explanation of these spectra would involve any new principle not already contained in the explanation of the appearance presented when there are only two twin planes, though the necessary formulæ would doubtless be more complicated.

Corresponding to a wave incident in any direction, in one component of a twin, on the twin plane, there are in general two refracted waves in the second component in planes slightly inclined to each other, and two reflected waves which also have their planes slightly inclined to each other, the angle of inclination, however, being by no means *very* small, as chlorate of potash is strongly double refracting. The planes of polarisation of the two refracted waves are approximately perpendicular to each other, as are also those of the two reflected waves; but on account of the different orientation of the two components of the twin, the planes of polarisation of the two refracted waves are in general altogether different from those of the incident wave and of its fellow, the trace of which on the twin plane would travel with the same velocity. In the plane of symmetry at any incidence, and for a small angle of incidence at any azimuth of the plane of incidence, the directions of the planes of polarisation of the two refracted waves agree accurately or nearly with those of the incident wave and its fellow. In these cases, therefore, an incident wave would produce hardly more than one refracted wave, namely, that one which nearly agrees with the incident wave in direction of polarisation. In these cases the colours are not produced. It appears, therefore, that their production demands that the incident wave shall be very determinately divided into two refracted waves, accompanied of course by reflected waves.

It seems evident that the thickness of the stratum affects the result through the difference of phase which it entails in the two refracted waves on arriving at the second twin plane. But whereas in the ordinary case of the production of colour by the interposition of a crystalline plate between a polariser and an analyser, we are concerned only with the difference of retardation of the differently polarised pencils which are transmitted across the plate, and not with the absolute retardation, it is possible that in this case we must take into account not only the difference of retardation for the differently polarised pencils which traverse the stratum, but also the absolute retardation; that is, the retardation of the light reflected from the second relatively to that reflected from the first twin plane.

21. I have not up to the present seen my way to going further. It is certainly very extraordinary and paradoxical that light should suffer total or all but total reflection at a transparent stratum of the very same substance, merely differing in orientation, in which the light had been travelling, and that, independently of its polarisation. It can have nothing to do with ordinary total internal reflection, since it is observed at quite moderate incidences, and *only within very narrow limits* of the angle of incidence.

RECENT PROGRESS IN CHEMISTRY[1]

THE progress of chemistry during the last year has been considerable, and a great deal of interesting and important work has been done. Nevertheless it cannot be said to have been a year productive of any very special discoveries. In physical chemistry the subjects connected with heat have occupied a good deal of attention, such as the heat of formation of chemical compounds, &c. Experiments on the liquefaction and solidification of gases by pressure and low temperature have also been continued, and, in addition to the results which were obtained some time since, we now know chlorine, not only as a liquid, but also as a crystalline solid. The same is true of hydrochloric acid, carbonic oxide, silicon fluoride, and assinuretted hydrogen.

Last year I referred to the work which was being done with hydroxylamine, and also mentioned that another analytical reagent of equal importance was claiming attention, viz. Emil Fischer's phenylhydrazine. The promise of new work which this substance gave has been fully realised, and it has proved useful, not only as an analytical reagent, but has been the means of producing a number of new and important products.

Work is still actively pursued on the pyrroline, pyridine, and quinoline series, and it is remarkable, as we have [illegible] for the production of bodies of this description [illegible] stantly discovered. Those of A. Behrmann and Hofmann obtain pyridine derivatives from citrazinic acid of Ha mann, who obtains them from malic acid, may be illustrations.

It is interesting to notice, in reference to the series, Ladenburg's experiments (*Ber.*, xvii. 772-[illegible] that the compounds formed by the union of [illegible] the iodides of the alcohol radicals, when strongly [illegible] substituted pyridines in the same way as Hofmann [illegible] time since that aniline, under like circumstances, [illegible] stituted anilines, such as toluidine, &c. Hofmann [illegible] 1200) has also found that conine hydrochloride, when [illegible] with zinc dust, yields a base he has named conyrine, [illegible] believes to be a propyl or isopropyl pyridine; also [illegible] treatment with hydriodic acid at 280°-300°, regenerates [illegible] which has exactly the same physiological action as [illegible] (though it is probably optically inactive). Ladenburg [illegible] xvii. 1196) has obtained a propylpyridine which, also [illegible] with sodium and alcohol, yields a base standing very [illegible] conine; it has many properties in common with [illegible] like it, is poisonous, acting in the same manner and [illegible] degree. It is, however, optically inactive, as might be [illegible] It will be remembered that Schiff (*Ann. Ch. Phys.*, [illegible] obtained a base very similar to conine from [illegible] and ammonia some years ago, but it did not appear [illegible] all its properties with that body. From the new [illegible] has been done in this subject we may now soon expect [illegible] the constitution of this base definitely established. Ladenburg has also succeeded in producing piperidine from pyridine, identity of this product with that obtained from [illegible] pepper has been established (*Ber.*, xvii. 513-518).

Hofmann, while continuing his work on the action of [illegible] in alkaline solutions in amides, has found the curious [illegible] nitriles are produced in considerable quantities [illegible] atom of carbon less than the amide—in fact, corresponding [illegible] the amines formed in the reaction, and are, in all [illegible] produced from them by the removal of the hydrogen [illegible] these nitriles can be converted into amides by [illegible] and again treated with bromine and alkali, it is evident [illegible] this means we can gradually work down step by step [illegible] member of the homologous series to another.

It will be remembered that Pechmann and Duisberg (*Ber.*, xvi. 2119-2128) succeeded in obtaining substituted [illegible] and their hydroxy derivatives by acting on acetic and [illegible] acetic acids with phenols. Pechmann (*Ber.*, xvii. 929) has now succeeded in obtaining coumarins by treating malic [illegible] phenols with sulphuric acid or chloride of zinc; [illegible] phenol he has obtained coumarin; with resorcinol [illegible] and with pyragallol, daphnetin, which gives all the [illegible] of the natural body.

Some very curious results have lately been obtained [illegible] ence to the destructive action of aluminium chloride [illegible] carbons. Friedel and Crafts communicated a paper [illegible] subject to this Society in 1882; it has now been further [illegible] by Auschütz, Immerdorff, and by Jacobsen (*Ber.*, xvii. [illegible]). They have found that this action consists in "a transference [illegible] the alcohol radical from one molecule of a hydrocarbon [illegible] another molecule of the same hydrocarbon." Thus ethylbenzene yields, on the one hand, benzene, and on the other, [illegible] and more highly methylated benzenes, orthodiethylbenzene [illegible] very rarely found among the products.

Last year I referred to the discovery of thiophene, or, more properly, thiophen, and its homologues by Victor Meyer. During the year our knowledge of this interesting body has been considerably extended, and its preparation rendered comparatively easy. H. E. Schultze (*Ber.*, xvii. 407) has shown that it is contained—as might be expected—in the [illegible] phuric acid used to purify crude benzene, and that if this composition be prevented by diluting the acid with a [illegible] bulk of water as soon as it is separated from the benzene, [illegible] thiophen which is doubtless present in the form of a sulphonic [illegible] may easily be recovered by hydrolysing, by merely passing steam into the acid liquid.

The synthesis of thiophen, recently effected by [illegible] and H. Erdmann (*Ber.*, xviii. 454) by merely distilling [illegible] succinate with phosphorous trisulphide (by which about [illegible] cent. of the theoretical yield is obtained), is also of [illegible] well as the production of methylthiophene [illegible]

[1] From the Annual Address of the President of the Chemical Society, Mr. W. H. Perkin, F.R.S., March 30, 1885.

rate by the same reagent. The methylthiophen, however, ears to be isomeric with that separated from coal-tar toluene Victor Meyer. According to Volhard and Erdmann, phen, when cooled in a mixture of carbon dioxide and ether, stallises like benzene. Paal's synthesis of methyl-phenyl-phen from aceto-phenone-acetone, and of thiophen-carboxylic l—which is easily resolved into carbon-dioxide and thiophen— n mucic acid, may also be referred to here.

One of the most interesting of recent researches is that of Nietzki and T. Benckser on hexhydroxybenzene ($C_6HO)_6$ r., xviii. 499)), which they have succeeded in obtaining from nilic (dinitrodehydroxyquinone). They find the diimido y obtained from this when treated with nitric acid, yields a luct of the composition $C_6H_{16}O_{14}$, which when treated with cing agents, yields this substance. They also find that n heated with concentrated nitric acid, hexhydroxybenzene onverted into a body having the remarkable formula $_{16}O_{14}$. This decomposes when heated to 100°, or when d with water, carbon dioxide being given off, and on adding sh solution to the residue or the boiled solution, orange yellow les of a potassium salt of the formula $C_6K_2O_6$ are obtained, h they have identified as potassium croconate, and they ve that the bodies obtained by Lerch (*Am. Chem. Pharm.*, r. 20) from the compounds of potassium carbonic oxide ed during the preparation of the metal) were hexyhydroxy-ne, tetrahydroxyquinone, and the compound $C_6H_{16}O_{14}$, n fact that the compound $C_6(OK)_6$ is present in "potassium nic oxide." From experiments on the remarkable sub-e $C_6H_{16}O_{14}$, they came to the conclusion that it is a com-d of $C_6O_6+8H_2O$, and is a quinone which they call tri-ylbenzene. This appears to be confirmed by the production intermediate hydroxy compounds, the following being the of products;—

$$C_6(OH)_6,$$
$$C_6(OH)_4O_2,$$
$$C_6(OH)_2O_4,$$
$$C_6O_6.$$

reference to agricultural chemistry Messrs. Lawes and t have contributed a most important and interesting paper Society (1884, pp. 305-407) on the ash of wheat-grain wheat-straw. They gave the analyses of no less than -two wheat-grain and wheat-straw ashes, every ash being duce of known history of growth as to soil, season, and ing, all the specimens having been grown at Rothamp-

Out of the many important deductions this paper con-he following are extremely interesting:—It appears, in ce to the grain, that on the whole there is great uniformity nineral composition under different conditions of manuring, d only it is perfectly and normally ripened. The influence on producing a much wider range in the mineral constitu-the grain than the manuring. This, however, is not the th the straw, as it is found that the amount of mineral nstituents found in the straw, and therefore in the op, have a very direct connection with the amounts e in the soil, but the amounts stored up in the grain e little influenced by the quantity taken up.

es the researches just referred to there has been a con-e amount of good work done, but it would be out of r me to refer to it more fully in this short review.

ear I took occasion to refer to the comparatively small of original work which was being prosecuted in this notwithstanding the increased number of laboratories greater facilities which existed for the encouragement of

It will be seen from the list of papers that the num-ght before the Society during the past year has not , but if the papers themselves are examined I think find that the amount of work done is somewhat larger, ertainly not so large as it should be; and it is to be at the spirit of research will be stimulated in the ies of the kingdom, and that men may be turned out not only more or less analysts, but thorough chemists. ot be contented with looking back with pride to what tors have done, but let us follow their example.

SOCIETIES AND ACADEMIES

LONDON

Royal Society, March 10.—"The Paralytic Secretion of Saliva." By J. N. Langley, M.A., F.R.S.

It has been shown by Claude Bernard and by Heidenhain that section of the chorda tympani nerve on one side, causes a slow continuous secretion from both sub-maxillary glands. Since the secretion which takes place on the side of the body on which the nerve is cut is called the "paralytic" secretion, that which takes place on the opposite side may be called the "anti-paralytic" or "antilytic" secretion. The author finds that the antilytic secretion becomes slower when the chorda tympani nerve is cut, and stops when, in addition, the sympathetic nerve is cut. It is, then, caused by nervous impulses sent out by a secretory centre in the medulla oblongata. This centre is in a state of increased irritability, for dyspnœa causes a much more rapid flow of saliva, and causes it sooner than it does normally. The paralytic secretion during the first day or two of its occurrence is also caused by stimuli proceeding from the central secretory centre; since the paralytic secretion is more copious than the antilytic secretion, and since dyspnœa causes a greater increase of the former than of the latter, it follows that the increase of irritability in the central secretory centre is greater on the side on which the chorda tympani has been cut than on the opposite side. In this state of increased irritability the central nerve-cells are probably stimulated by the blood supplied to them. The paralytic secretion in its later stages is probably brought about by a similar state of increased irritability in nerve-cells in the gland itself, *i.e.* of a local secretory centre. In its later stages the secretion continues after severance of all the nerve-fibres proceeding from the central nervous system to the gland; it is, however, increased by dyspnœa, stopped by apnœa, and by large doses of anæsthetics, which indicates that it is brought about by nerve-impulses. The peripheral end of the chorda tympani remains irritable for two to three weeks, which is a further indication that the secretory nerve-fibres are connected with some, at any rate, of the many nerve-cells present in the gland. Notwithstanding the continuous paralytic secretion, the gland-cells become slightly more mucous than normal; except for this and a decrease in size they remain normal. They secrete as usual when the sympathetic nerve is stimulated.

Geological Society, March 25.—Prof. T. G. Bonney, D.Sc., LL.D., F.R.S., President, in the chair.—Charles De Laune Faunce De Laune and William Hill were elected Fellows of the Society.—The following communications were *read*:—On the relationship of *Ulodendron*, Lindley and Hutton, to *Lepidodendron*, Sternberg, *Bothrodendron*, Lindley and Hutton, *Sigillaria*, Brongniart, and *Rhytidodendron*, Boulay, by Robert Kidston, F.G.S.—On an almost perfect skeleton of *Rhytina gigas=Rhytina Stelleri* ("Steller's sea-cow") obtained by Mr. Robert Damon, F.G.S., from the Pleistocene peat-deposits on Behring's Island, by Henry Woodward, LL.D., F.R.S., F.G.S. The author spoke of the interest which palæontologists must always attach to such animals as are either just exterminated or are now in course of rapid extirpation by man or other agents. He referred to the now rapid destruction of all the larger Mammalia, and expressed his opinion that the African elephant, the giraffe, the bison, and many others, will soon be extirpated unless protected from being hunted to death. The same applies to the whale- and seal-fisheries. He drew attention to a very remarkable order of aquatic animals, the *Sirenia*, formerly classed with the Cetacea by some, with the walruses and seals by others, and by De Blainville with the elephants. He particularly drew attention to the largest of the group, the *Rhytina*, which was seen alive and described by Steller in 1741. It was then confined to [illegible] Island and Copper Island. In 1768 [illegible] believed to have been entirely exterminated. It was a Herbivore, living along the shore in shallow [illegible] easily taken, being without fear of man. Its [illegible] it weighed often three or four tons. The author [illegible] some of the leading points in the anatomy of the [illegible] indicated some of the characters by which it [illegible] tinguished. He referred to the present [illegible] of the Sirenia:—*Manatus* with three species, [illegible] *latirostris*, occupying the shores of Florida and the [illegible] *M. americanus*, the coasts of Brazil and the great [illegible] and Orinoco; *M. senegalensis*, the west coast of Africa, rivers Senegal, Congo, &c. *Halicore*, with three species, namely, *H. tabernaculi*, the Red Sea and east coast of Africa; *H. dugong*, Bay of Bengal and East Indies; *H. australis*, and East Australia. The fossil forms number [illegible] and twenty-nine species, all limited to England, Belgium, France, Germany, Austria, Italy, Malta, and Egypt to the United States and Jamaica. The author [illegible] details as to the dentition of fossil species, of which *Halitherium* and *Prorastomus* are the two most remarkable types. With regard to the geographical area occupied by the group by the Sirenia, the author pointed out that two lines drawn N. and 30° S. of the equator will embrace all the species found living. Another line drawn at 60° N. will [illegible] 30° and 60° N. the area once occupied by the [illegible] species. He looked upon *Rytina* as a [illegible] the old Tertiary group of Sirenians, and its position as an "*outlier*" of the group now swept away.

Physical Society, March 28.—Prof. Guthrie, [illegible] the chair.—The President announced that the [illegible] 9 would be held at Bristol; further particulars would be communicated to the members.—Mr. Hawes was elected [illegible] the Society.—The following papers were read on [illegible] machines, by Mr. Joseph Edmondson. Calculating-machines are of two classes—the automatic and the [illegible] former were invented by Mr. Charles Babbage between [illegible] and 1834, and were designed mainly for the [illegible] tables. The difficulties against which this inventor [illegible] and the perseverance he displayed in the construction of the "difference-engine" he had imagined are [illegible] history. On account of the great cost and high degree of complexity of this machine it was never completed. Of calculating-machines of the present day being of the automatic class the first example of which a [illegible] and incomplete instrument by Sir Samuel Morland [illegible] From 1775 to 1780 the Earl of Stanhope invented [illegible] which were a great advance upon those of Sir S. Morland. In these is found the "stepped reckoner," the basis of [illegible] instruments. This "stepped reckoner" was improved by Thomas de Colmar, who, in 1851 produced a machine which is now largely in use. This machine, somewhat [illegible] detail and construction, is now made by Mr. Tate, [illegible] and Mr. Edmondson has patented a modification [illegible] form of the instrument is circular, by which means a [illegible] instead of a limited slide is obtained. A collection of valuable instruments, which had been kindly lent for the occasion, were exhibited. A discussion followed in which Babbage, Mr. Tate, Prof. McLeod, Dr. Shaw, the [illegible] Harley, Mr. Whipple, Prof. Ayrton, and other [illegible] part.—On the structure of mechanical models illustrating properties in the ether, by Prof. G. F. Fitzgerald. He had recently constructed and described before the Royal Irish (NATURE, March 26, p. 498). This model was [illegible] but the author now shewed how a tri-dimensional [illegible] be imagined, though probably mechanical difficulties would render its actual construction impossible. Each [illegible] ether is to be represented by a cube on each side of which is a paddle-wheel. Thus on any face of the cube there are four paddle-wheels. Now, if any opposite pair of [illegible] by different amounts, they will tend to pump [illegible] the whole is immersed into or out of the cube, and if [illegible] the cube be elastic there will be a stress which will [illegible] this differential rotation of the wheels. If two [illegible] rotate by different amounts, they may each [illegible] do, and thus the stress will depend on the [illegible] the differential rotations of these opposite pairs of [illegible] n represent the angular rotation of one pair, and [illegible]

the stress will depend upon $\frac{d\eta}{dx} - \frac{d\zeta}{dy}$. In order that these heels may not similarly work with any other wheel, it is ary to place diaphragms dividing the cube into six cells, pyramid standing on a face of the cube. They must be le that liquid may not be able to pass from one cell to r through the diaphragm or beside the paddle-wheels; to this the floats on the paddle-wheels would have to be down while passing the diaphragms. Thus the energy orsion of such a medium would depend upon

$$\left(\frac{d\zeta}{dy} - \frac{d\eta}{dz}\right)^2 + \left(\frac{d\xi}{dz} - \frac{d\zeta}{dx}\right)^2 + \left(\frac{d\eta}{dx} - \frac{d\xi}{dy}\right)^2.$$

Maxwell has shown that this is also true for the ether. The of the cubes should be filled up with diaphragms, past the paddles should pump liquid, and whose elasticity be the means of storing electrostatic energy in the n. The most complicated results follow from supposing es of the cubes of which the medium is constructed to ifferent elasticities. Such a structure represents a crystall-dium, and vibrations would be propagated in it according the same as those regulating the transmission of light in ine media. If the cubes were twisted, the structure be like that of quartz or other substances rotating the of polarisation. To represent magnetic rotation of the f polarisation it would be necessary to introduce some ism connecting the ether with matter. The author, in ion, insisted upon a view which regards the vibrations ting light to be of the nature of alterations of structure, of displacements executed in a medium possessing the ies of an elastic jelly.—At the close of the meeting the ng instruments were exhibited and described in a conver- manner by their makers: a chrono-barometer and a thermometer by Mr. Stanley. These instruments con- of clocks regulated by pendulums formed in the first ent of a mercurial barometer, and in the second of a barometer inclosed in a hermetically-sealed air-chamber, osed barometer thus acting as an air-thermometer. In- of pressure in the one case, and of temperature in the auses the mercury to rise, and thus accelerates the pen- By the gain or loss of time the mean pressure or tem- e can be calculated for any period.—A heliostat and a meter, by Mr. Conrad W. Cooke. The galvanometer led to show the internal current in a cell. The battery re in two cells connected by four glass tubes in multiple d around an astatic needle. The glass work is by Mr. nam.—A spherometer, by Mr. Hilger, was made of m, and combined lightness with rigidity. By an l contact the maker asserted that measurements could be one-millionth part of an inch.—Col. Malcolm exhibited a ope and a binocular field-glass in which the two eye- ere separately adjustable; and Dr. Watts exhibited a odification of a quadrant electrometer.

l Microscopical Society, March 11.—Rev. Dr. Dall- .R.S., President, in the chair.—Mr. Crisp exhibited class microscope with movable stage, Tolle's clinical pe, Seibert's portable microscope, and Swift's micro- examination of skin of sheep having a very long work- nce, Griffiths' and Bertrand's objective adapters and a of "finder."—Mr. H. G. Madan exhibited some new glass, having found that a combination of ordinary blue a peculiar bluish-green glass, known as "signal-green" s much more convenient than the usual glass cell filled tion of cuprammonium sulphate.—Mr. Baker exhibited ect-boxes in book-form for placing on a shelf with e objects then lying flat.—Dr. C. v. Zenger's letter was ribing a new mounting medium consisting of tribromide in bisulphide of carbon, and giving a refractive index ·6696 to 1·7082. An improved slide for viewing the both sides was also described.—Mr. C. H. Hughes's n was read of a stage for use with high powers to he decentring of the condenser, especially when used mersion contact. Vertical, horizontal, and oblique re given to the slide, while the stage remains station- n be rotated.—Mr. E. M. Nelson exhibited a drawing bacillus showing the flagella.—Mr. J. Mayall, jun., the original ruling machine of the late Herr F. A. hich was exhibited to the meeting. The foundation achine was a dividing engine calculated to produce visions far finer than could be marked by any ruling liscovered. The division-plate [redacted] circles of "dots," and these were supplemented by extremely fine graduations on two bands of silver imbedded near the edge, which were viewed by means of two compound microscopes, each provided with eyepiece screw micrometers of special construction. The movement of rotation was effected by a fine tangent screw acting on a worm on the vertical edge of the division-plate. The method employed by Herr Nobert for obtaining the minute divisions of his test-plates (ranging from 1-1000th to 1-20,000th of a Paris line) was to convert the radius of the division-plate into a lever to move the glass plate on which the rulings were made at right angles to the motion of the ruling point. For this purpose he attached to the centre of the rotating division-plate a bent arm, on which slid a bar of silver, having at one end a finely-polished steel point which could be adjusted by a scale and vernier so as to project more or less beyond the centre of the division-plate or axis of rotation. The radius of the division-plate thus became the long arm of the lever, whilst the radius of the projection of the polished steel point beyond the axis of rotation formed the short arm, the centre of the division-plate being the fulcrum. The motion of the short arm of the lever was communicated by contact with an agate plate to a polished steel cylinder adjusted to slide at right angles to the movement of the ruling point in V-shaped bearings of agate. The steel cylinder carried a circular metal table, on which the glass plate to be ruled was fixed by wax and clamps. The arrangement for carrying the diamond point was, he believed, wholly designed by Herr Nobert, and was a most ingenious combination of mechanism.—Mr. Mayall referred briefly to the preparation of the glass plates for the rulings, which, he said, were of specially "mild" composition. It was abundantly proved by Herr Nobert's work that the perfection of the mechanical part of the dividing-engine was not the only difficulty which he had understood, and conquered. There was a still greater difficulty which he had understood, and in which he had met with a success that gave him pre-eminence in this department of micro-physics, and that was the preparation of the diamond ruling-points. The description of these was deferred until the next meeting.—Mr. C. Beck exhibited a modification of the "complete" lamp fitted with a shallow glass reservoir instead of the original one of metal, also a vertical illuminator with a new form of diaphragm.—Dr. Van Heurck's note was received, sending a copy of Prof. Abbe's opinion on the photographs of the "beads" of *A. pellucida*, in which he stated that he had no reason to doubt the reality of the beads.—Dr. J. D. Cox's note was read as to actinic and visual foci.—Mr. F. Kitton's remarks in commendation of balsam of Tolu for mounting were read.—Dr. Ord exhibited and described some objects illustrating the erosion of the surface of glass when exposed to the action of carbonate of lime and a colloid.—Mr. J. W. Stephenson read his paper, on a new catodioptric illuminator, having an aperture exceeding that of any existing objective, or equal to 1·644 N.A. in flint glass, and 1·512 N.A. in crown glass.—Mr. Cheshire and Mr. E. Chayne's paper on the pathogenic history of a new bacillus (*B. alvei*) was then read, in which it was shown that the disease attacking bees, and known as "foul brood," was due to a bacillus. They had also discovered that the disease yielded readily to treatment which consisted in feeding the larvæ with a syrup containing 1-600 per cent. of phenol. A detailed explanation was given of the methods adopted in tracing out the life-history of the bacillus, and a series of tubes and bottles in which its propagation had been carried on were exhibited.—Mr. Fowke read a paper on the first discovery of the comma bacillus of cholera. He showed that the bacillus was known and recognised thirty-five years ago by two Englishmen, Messrs. Brittain and Swayne. It was pointed out that it was by the breaking up of the rings discovered by original observers that the so-called "comma" bacilli were formed.—Sixteen new Fellows were proposed and elected.

MANCHESTER

Literary and Philosophical Society, February 10.—Prof. W. C. Williamson, LL.D., F.R.S., President, in the chair.—On some undescribed tracks of invertebrate animals from the Carboniferous rocks, and on some inorganic phenomena, simulating plant remains, produced on tidal shores, by Prof. W. C. Williamson, LL.D., F.R.S., President. Prof. Williamson's memoir first contained descriptions and figures of a new form of Chrossocorda, which he named *C. tuberculata*, from the Yoredale rocks of Stonyhurst, in Lancashire, which genus has hitherto been found only in Palæozoic rocks of much older age than the Yoredale beds. Reciting the views of Schimper and

others, who believe that the genus Chrosnachorda represents some fucoidal form of Palæozoic life, the author regards the various modifications of it as consisting of tracks of marine animals, probably crustaceans. He assigns the name of *Chrossochorda tuberculata* to that now described. A second form of track, of a different type, was found by Mr. J. W. Davis, F.G.S., of Chevinedge, near Halifax. It consists of a line of curved footprints in groups of eight—four on each side—the successive groups varying from five-eighths of an inch to two inches apart from each other. The specimen described was found in a quarry of Yoredale beds, near Hawes. The author assigns to it the name of *Protichnites Davisi*, after its discoverer. Casts of two series of markings, produced by water, were exhibited and described. One of these series represented branching forms easily mistaken for fucoidal remains. They were in reality casts, made in plaster of Paris, of remarkable drainage lines left by the retiring tide, on the sandbanks at Llanfairfechan, in North Wales. The second series consisted of allied objects, but in this case drainage lines had combined with ripple marks to produce an effect easily mistaken for the geometrically arranged scale-leaves of some cycadean stem. These casts were obtained from sandbanks to the north of Barmouth. The author called attention to the controversy bearing on these subjects still in progress, especially between Prof. Nathorst and the Marquis of Saporta, and renewed an objection, recorded in more than one of his previous publications, to such anomalous objects as those in dispute being made use of, when attempting to frame, from Palæontological evidences, a pedigree of the vegetable world.

CAMBRIDGE

Philosophical Society, March 16.—Prof. Foster, President, in the chair.—The following communications were made:—Further remarks on the urea-ferment, by Mr. Lea.—On some points in the anatomy of Nebalia, by Mr. Weldon.—Observations on the constitution of callus, by Mr. Walter Gardiner.—Observations on vegetable proteids, by Mr. J. R. Green.—On the development of K, E, I, G in powers of the modulus (Part II.), by Mr. J. W. L. Glaisher.

SYDNEY

Linnean Society of New South Wales, January 28.—Annual General Meeting.—The President, C. S. Wilkinson, F.L.S., in the chair.—The President delivered an address upon the Pleistocene period, and its influences upon the present distribution of the fauna and flora of Australia. He gave also a short review of the work of the Society during the past year.—It was resolved that ladies may be admitted upon election as associates of the Society, with all the privileges of ordinary members except the right to attend the monthly meetings, at the reduced subscription of one guinea, without entrance fee.—The following papers were read:—A monograph of the Australian sponges: Part iv., the Myxospongiæ, by R. von Lendenfeld, Ph.D. In this paper the Australian species are described. (The author partly adopts the view of Sollas regarding the separation of the Halisarcidæ and Gumminæ.) The structure of Bajalus, a new genus of Halisarcidæ, is described. The subdermal cavities are remarkably developed. Ameboid wandering cells were found in a dense layer beneath the outer skin. Gland cells are described. Sexual products mature only in the innermost part. The gastral cavity serves as a marsupium. The anatomy of *Chondresia Ramsayi*, n.sp., *Chondrilla papillata*, n.sp., and *corticata*, n.sp., shows some points of interest. Peculiar subdermal cavities are described in the former. The two latter possess a special cortical skeleton.—The method of section-cutting with some improvements, by R. von Lendenfeld, Ph.D.—*Amœba parasitica*, a new parasitic Protozoan infesting sheep, by R. von Lendenfeld, Ph.D.—The meteorology of Mount Kosciusko, by R. von Lendenfeld, Ph.D.—The Glacial period in Australia, by R. von Lendenfeld, Ph.D. The author gives the results of his recent expedition to the central part of the Australian Alps in this paper, as far as they bear on the above question. He ascended the two highest peaks in Australia and found on the plateau which surrounds them undoubted glacial remains in the shape of *roches moutonnées* in many places above 5600 feet. He concludes that Australia was affected by a glacial period at the same epoch as New Zealand, but that, owing to the lowness of the mountains (only 7256 feet the highest peak), the low latitude, and the warm and dry winds from the interior, the glaciers attained but small dimensions, and only covered an area of about 100 square miles. He considers it probable that no other glaciers existed in Australia at the time, as even those on the highest elevation of the continent are [illegible] Proteaceæ, by the Rev. W. Woolls, Ph.D., F.L.S. [illegible] snake from the Barrier Ranges, by William Macleay, &c. The description is here given of a species to [illegible] which the specific name of *Rama spp* is affixed. [illegible] of it were exhibited, as well as specimens of *Furina* [illegible] and *Delma*, from the same locality.

PARIS

Academy of Sciences, April 6.—M. Bailet, Pres[ident] the chair.—Obituary notice of M. Rolland, [illegible] Section for Mechanics, who died on March 31.—[illegible] —Remarks on the agreement between geological and [illegible] epochs, by M. Faye. These remarks are made [illegible] with his work, "Sur l'Origine du Monde," recently [illegible] the Academy, in which he develops his theory [illegible] evolution of the solar system. Here this theory is [illegible] fresh arguments drawn from thermodynamics, biology, [illegible] physics.—On the artificial and supplementary [illegible] for soil of different qualities, by M. A. Müntz.—[illegible] by numerous examples that such manures should be [illegible] only according to the nature of the crops to be [illegible] according to the character of the lands requiring [illegible] —On the resistance offered by a fluid in rapid [illegible] weight to the varied movement of a solid sphere [illegible] when the velocities are continuous, but so slow that [illegible] and products may be neglected, by M. J. Boussinesq.—[illegible] "polhodie," a curve introduced by Poinsot into [illegible] on the rotation of bodies, by M. A. Mannheim.—[illegible] faction and solidification of ferrous and of the [illegible] nitrogen, by M. K. Olszewski.—On the amides of [illegible] adipose group, by M. L. Henry.—Funeral [illegible] at the obsequies of M. Rolland on April 7, by MM. [illegible] Schlösing.

STOCKHOLM

Royal Academy of Sciences, March 11.—[illegible] communicated a paper by A. Slidanow on the [illegible] intermediate orbit of the comet of Faye-Möller when [illegible] vicinity of Jupiter in 1841.—Prof. Mittag-Leffler [illegible] (1) on periodical functions with a discontinuous [illegible] the first kind, by himself; and (2) simulations [illegible] matician, Petrus de Dacia, and his writings, by [illegible] The Secretary, Prof. Lindhagen, presented [illegible] Linnæus on the species of plants determined and [illegible] the nature, represented according to the works of Linnæus, compared with the corresponding views of Darwin, by [illegible] G. Agardh; (2) Desmidiæ collected during the [illegible] Nordenskiöld to Greenland in 1870, by Prof. [illegible] described by Dr. O. Nordstedt.

EDWARD STANFORD'S NEW PUBLICATIONS.

Now Ready, Cheap Edition, Fcap. 8vo. Cloth, with 6 Maps and 25 Illustrations, 2s.

EPPING FOREST. By EDWARD NORTH BUXTON, Verderer.

"Mr. Buxton goes about his work in a thoroughly practical way. His book is plentifully furnished with accurate maps, and about thirty pages are occupied with simple and clear directions as to the several walks which may be taken through the Forest. It may be safely said that any one who carefully follows Mr. Buxton's directions will obtain a perfectly new conception of the Forest and its peculiar beauties. The book is illustrated by many charming drawings of forest scenes, and by numerous delicately executed woodcuts of birds and flowers."—*Times*.

"Mr. Buxton has rendered a great service to the public in general, and to Londoners in particular, in preparing a book which must henceforth take the first place among the Guides to Epping Forest."—*Saturday Review*.

Just Published. Small Post 8vo. with Plan, Cloth, 1s.

VISITOR'S GUIDE to SIENA and SAN GIMIGNANO. By J. L. BEVIR, M.A., Author of "Visitor's Guide to Orvieto."

Third Edition, Revised, 18mo. Cloth, 1s. 6d.

* Bottles charged 2/- per doz., and allowed at the same rate if returned; but they must be paid for with the Beer.

Neither sugar, saccharum, nor any of the many new Brewing Materials are used in the manufacture of the "S. N." Stout; it is Brewed entirely from the finest Malt and Hops; it is, too, more hopped than Stout is generally; therefore, besides being very nutritious, it is an excellent Tonic and particularly suited for invalids, ladies nursing, or anyone requiring a good strengthening beverage. It is a "Sound Nutritious" Tonic, and very much recommended by Medical men.

1500 Engravings,
Price 5s. 6d.

The GROCERS' COMPANY'S SCHOLARSHIPS for ORIGINAL RESEARCH in aid of SANITARY SCIENCE.

The Scholarships, each of the value of £250 a Year, and open only to British Subjects, are founded with a view to encourage the making of exact Researches into the Causes of important Diseases, and the means by which they may be prevented or ameliorated. The Appointment and Re-appointment to these Scholarships will be made in the month of MAY next.

Applications to be made during the month of APRIL, by Letter addressed to the CLERK of the Grocers' Company, Grocers' Hall, London, E.C., from whom Copies of the Scheme can be obtained.

PRIZE OF ONE HUNDRED POUNDS.

The Council of the Linnean Society of New South Wales hereby again offers a PRIZE of ONE HUNDRED POUNDS for the Best Essay on "The Life-History of the Bacillus of Typhoid Fever." The Essay must be based entirely on original research, the details of which and of the methods employed are to be fully explained; must be in English; must be distinguished by a "motto," accompanied by an envelope containing the author's name; and must be delivered at the Society's House, 54, Phillip Street, Sydney, on or before DECEMBER 31, 1885.

LONDON HOSPITAL AND MEDICAL COLLEGE,

MILE END, E.

The SUMMER SESSION will commence on Friday, May 1. Intending Students are advised that under the new regulations of the Royal College of Physicians and the Royal College of Surgeons, it is exceedingly advantageous to enter for the Summer Session. Students now entering are also eligible for the Entrance Scholarships in September.

The Hospital contains nearly 800 beds, and is the largest general Hospital in Great Britain.

General Fee for Lectures and Hospital Practice, 90 guineas in one sum, or 100 guineas in three instalments. The Resident and other Hospital Appointments are free to full Students.

Special entries may be made for Medical and Surgical Practice, also for the course of Practical Surgery.

The London Hospital is now in direct communication by rail and tram with all parts of the Metropolis, and the Metropolitan, Metropolitan District, South Eastern, and East London Railways have stations within a minute's walk of the Hospital and College.

For Prospectus and particulars apply to

MUNRO SCOTT, Warden.

ST. THOMAS'S HOSPITAL MEDICAL COLLEGE,

ALBERT EMBANKMENT, S.E.

The Summer Session will commence on May 1. Students who have passed a Preliminary Examination are informed that, under the Regulations of the Examining Board in England, it is an advantage to begin in the Summer Session: those entering in summer are also eligible to compete for the Science Scholarships of £100 and £60, awarded in October.

There are numerous Prizes and Scholarships, and all Appointments are open to Students without extra charge.

Special Classes for the Examinations of the University of London are held throughout the year. A Register of Approved Lodgings and of Private Families receiving Students to reside is kept in the Secretary's office.

Prospectus and all particulars can be obtained from the Medical Secretary, Mr. G. REYNOLDS.

W. M. ORD, Dean.

THE MIDDLESEX HOSPITAL MEDICAL SCHOOL.

The SUMMER SESSION, 1885, will commence on May 1. The Lectures and Demonstrations are arranged with a view to meet the requirements of Candidates preparing for Examination under the new Competitive Scheme.

An ENTRANCE SCHOLARSHIP, value £63, will be offered for Competition to Students commencing their Medical Education in May. The Examination will be in Classics, Mathematics, or Natural Sciences, and will commence on April 29. Two Entrance Scholarships of the Annual Value of £25 and £20 respectively, tenable for two years, and a Science Scholarship value £50, will be offered for competition at the beginning of the Winter Session.

For Prospectus containing Particulars as to other Scholarships, Resident Appointments, Fees, &c., apply to the DEAN, or the Resident Medical Officer at the Hospital.

ANDREW CLARK, Dean.

ST. GEORGE'S HOSPITAL MEDICAL SCHOOL.

HYDE PARK CORNER, S.W.

The Summer Session will commence on FRIDAY, May 1.

Five Entrance Scholarships—

The William Brown £100 Exhibition;
The William Brown £40 Exhibition;
Two Brackenbury Prizes, £50 each;

And various other Prizes, are open to Competition.

Full Particulars, with the Subjects of Examination, may be obtained on application to

WILLIAM WADHAM, M.D., Dean of the School.

3½ WRAY TELESCOPE and STRONG GARDEN STAND: First-Class Instrument. Test Objects and Full Information, T. CLARKSON, Ashwick Hall, Leicester.

LIVING SPECIMENS FOR THE MICROSCOPE.

GOLD MEDAL awarded at the FISHERIES EXHIBITION.

THOMAS BOLTON, 57, NEWHALL STREET, BIRMINGHAM, who has just week sent to his subscribers [illegible] drawing and description. He has also on hand [illegible] Actinia grandis, Cuchetium spectabile, Cyanea [illegible] linus, Lumbrus ceruophili, Stentors, [illegible] Amœbæ, Vorticellæ, Crayfish, and other Specimens [illegible] Biological Laboratory work.

Weekly Announcements will be made in this [illegible] supplying.

Specimen Tube, One Shilling, post free.

Twenty-six Tubes in course of [illegible] or Twenty Tubes for one full.

Portfolio of Drawings, Ten Parts, 1s. each.

KING'S COLLEGE, LONDON

MEDICAL DEPARTMENT.

The SUMMER SESSION will begin on FRIDAY, May 1.

In addition to the regular Medical Courses there will be Courses and Demonstrations on Botany, Practical Chemistry, Practical Experimental Physics, and the Tutors' Class for the Preliminary Examination and the University of London. There are Special Classes all the ordinary Medical Examinations without extra Fee. Classes for the Preliminary Scientific and Intermediate M.B. Exam of the University of London and the Primary Fellowship of the College of Surgeons. Students entering in the Summer Session will be eligible compete in September next for the two Entrance Warneford Scholarships £30, for two Science Exhibitions given by the Committee of Council for two Sambrooke Science Exhibitions.

For the Prospectus, apply personally, or by Post, to [illegible] CUNNINGHAM, Esq., King's College, London.

SCIENCE AND ART DEPARTMENT

50 PER CENT. GRANT FOR THE PURCHASE OF SCIENCE COLLECTIONS AND APPARATUS FOR TEACHING [illegible] AND MINERALOGY. NEW LISTS and FORMS [illegible] Application is to be made supplied by

Burnett and Oliver on Recurrent Dropsy of Left Middle Ear—Walton on Neglect of Ear-symptoms in Diagnosis of Diseases of Nervous System—Putnam on Examination of Spinal Cord in Polio-Myelitis of Adult—Fox on Pathological Anatomy of Cerebro-Spinal Axis of Chronic Myelitis—Schmidt on Two Cases of Compression of Spinal Cord by Sarcomatous Growths—Segrin on American Method of giving Potassium Iodide, and on Efficacy of Iodide of Potassium in Non-Syphilitic Organic Diseases of Nervous System. By J. A. Ormerod, M.D.

MACMILLAN & CO., LONDON.

NORTH BRITISH AGRICULTURIST,

the only Agricultural Journal in Scotland, circulates extensively among Landowners, Farmers, Resident Agents, and others interested in the management of land throughout the United Kingdom.
The AGRICULTURIST is published every Wednesday afternoon in time for the Evening Mails, and contains Reports of all the principal British and Irish Markets of the week.
The special attention of Land Agents is directed to the AGRICULTURIST as one of the best existing papers for Advertising Farms to be Let and Estates for Sale.
Advertisers addressing themselves to Farmers will find the AGRICULTURIST a first-class medium for reaching that Class.
Price 3*d.* By post 3½*d.* Annual Subscription, payable in advance, 14*s.*
Offices—377, High Street, Edinburgh; and 345, Queen Victoria Street, London, E.C.
Money Orders payable to Charles Anderson, Jun., Edinburgh.

Now Ready, in Demy 8vo, 54 Pages. With Illustrations. Price 1*s.*

THE SCOTTISH MARINE STATION FOR SCIENTIFIC RESEARCH, GRANTON, EDINBURGH, ITS WORK AND PROGRESS: A POPULAR ACCOUNT OF THE RESULTS OBTAINED SINCE THE OPENING OF THE STATION IN APRIL, 1884, AND OF THE RESEARCHES NOW IN PROGRESS.

Edinburgh: DAVID DOUGLAS, and all Booksellers.

MUTUAL LIFE ASSURANCE.

SCOTTISH PROVIDENT INSTITUTION

EDINBURGH—6, ST. ANDREW SQUARE. LONDON OFFICE—17, KING WILLIAM STREET, E.C.

The ATTENTION of ASSURERS is directed to the SPECIAL ADVANTAGES obtainable in this Society, in respect of
ECONOMY—EQUITY—SAFETY.

ECONOMY.—The Premiums are, in many cases, 20 to 25 per cent. under the usual rates, so that a Policy for £1250 may generally be had for the yearly payment which would elsewhere assure £1000 only.

EQUITY.—The whole Surplus is divisible among the Policy-holders themselves, on an equitable principle—preference given to those by whose early death there is a *loss* to the other Members. From this source large additions have been made, and may be expected in the future.

SAFETY.—The Business (which for ten years has exceeded a Million yearly) is of the most select character, and is conducted at the smallest cost.

The expenses, which are less than in any Office transacting so large a business, were last year under 9 per cent. of the Premiums, and little over 6 per cent. of the year's Income.

THE FUNDS accumulated from Premiums exceed **£5,000,000**, the increase last year being £333,383.

Only two Offices in the Kingdom (both older) have as large a Fund.

Claims under Policies now payable a Month after Proof.

Reports, with Tables of Premiums, &c., on Application.

J. MUIR LEITCH, London Secretary. JAMES WATSON, Manager.

WESLEY COLLEGE, SHEFFIELD.

(AFFILIATED TO THE LONDON UNIVERSITY, 1844.)

GOVERNOR AND CHAPLAIN ... ... REV. W. H. DALLINGER, LL.D., F.R.S., &c., &c.
HEAD MASTER ... H. M. SHERA, ESQ., M.A., LL.D.
SECOND MASTER ... C. J. SCOTT, ESQ., M.A., Scholar and Prizeman (Camb.)
FIRST MATHEMATICAL MASTER ... ... THOS. HUGH MILLER, ESQ., B.A. (Wrangler) Cloth

And TWENTY ASSISTANT MASTERS and PROFESSORS.

In addition to Classical, Mathematical, English, and Commercial Subjects, BIOLOGY, PHYSICS, and CHEMISTRY, the Modern Languages of Europe, Hebrew and Syriac, Vocal and Instrumental Music, and Drawing are taught by Accomplished Professors.

The REV. W. H. DALLINGER, LL.D., F.R.S., has undertaken the PROFESSORSHIP of NATURAL SCIENCE, and gives Weekly Lectures and Class Instruction in PRACTICAL ZOOLOGY, BOTANY, &c.

CHEMISTRY is taught by R. W. LANCASTER, ESQ., B.A. (1st Class Nat. Science), Christ Church, Oxford; and a Course of LECTURES on PHYSICS is delivered each Term by A. H. ALLEN, ESQ., F.C.S. SCHOLARSHIPS are AWARDED worth, in the aggregate, 300*l.* a year.

The JUNIOR SCHOOL is in excellent efficiency. Permanent Staff, T. S. COX, ESQ., B.A. (London), and three TRAINED Masters. CHEMISTRY, R. W. LANCASTER, ESQ., B.A. (Oxon); MUSIC and SINGING, J. MIDDLETON, ESQ., Bac. Mus. (Camb.)

PROSPECTUSES may be obtained by Application to the GOVERNOR or HEAD MASTER

THE SPRING TERM WILL COMMENCE ON TUESDAY, APRIL 28.

Next week. Medium 8vo, Price 21s.

A TEXT-BOOK of PHARMACOLOGY, THERAPEUTICS, and MATERIA MEDICA

By T. LAUDER BRUNTON, M.D., D.Sc., F.R.S.,

Fellow of the Royal College of Physicians; Assistant Physician and Lecturer on Materia Medica at St. Bartholomew's Hospital; Examiner in Materia Medica in the University of London, in the Victoria University, and in the Royal College of Physicians, London; late Examiner in the University of Edinburgh.

ADAPTED TO THE UNITED STATES PHARMACOPŒIA BY FRANCIS H. WILLIAMS M.D. BOSTON, MASS.

BY THE SAME AUTHOR.

In the Press,

DISORDERS OF DIGESTION: THEIR CONSEQUENCES AND TREATMENT

This work contains, in addition to the Lettsomian Lectures, a number of other Papers by the Author on similar subjects.

Demy 8vo.

MACMILLAN & CO., London.

Now Ready, in Crown 8vo, cloth. Price 7*s. 6d.*

PROPERTIES OF MATTER.

By P. G. TAIT, M.A., Sec. R.S.E.,

Formerly Fellow of St. Peter's College, Cambridge, Professor of Natural Philosophy in the University of Edinburgh.

CONTENTS:—Introductory.—Some Hypotheses as to the Ultimate Structure of Matter.—Examples of Terms in Common Use as Applied to Matter.—Time and Space.—Impenetrability, Porosity, Divisibility.—Inertia, Mobility, Centrifugal Force.—Gravitation.—Preliminary to Deformability and Elasticity.—Compressibility of Gases and Vapours.—Compression of Liquids.—Compressibility and Rigidity of Solids.—Cohesion and Capillarity.—Diffusion, Osmose, Transpiration, Viscosity, &c.—Aggregation of Particles.

THE "CHALLENGER" EXPEDITION

port on the Stalked Crinoidea Collected during the "Challenger" Expedition. By P. Herbert Carpenter, M.A., D.Sc. 4to, pp. 440, with 69 Plates. (London: Printed for Her Majesty's Stationery Office.)

THE Stalked Crinoids," says Mr. Murray in his prefatory notice to this Report, "both on account their rarity and their palæontological relations, are haps the most interesting and remarkable of deep-sea imals, and have been in a special manner associated h the *Challenger* Expedition. The joint work of the e Sir C. Wyville Thomson and Dr. W. B. Carpenter, t on *Comatula* and afterwards on *Pentacrinus*, together h the discovery by Prof. G. O. Sars of *Rhizocrinus* off Lofoten Islands in 1864, led directly to the expe- ions of the *Lightning* and the *Porcupine* in 1868 and following years; and was thus indirectly concerned the despatch of the *Challenger* Expedition in 1872." t only for these reasons, but also on account of the eptional value of Dr. P. H. Carpenter's Report, we ll give it a full notice.

Every scientific Palæontologist regards the group of *noidea* with special interest. Not only do its fossilized letons present themselves—frequently in a state of mirable preservation—in almost all marine limestones n the Lower Silurian to the present time; but they not unfrequently found to furnish by their accumula- no inconsiderable proportion of the calcareous mate- of such formations. And in the course of this long cession they exhibit a number of remarkable changes ype, each characteristic of a particular epoch. The st singular errors formerly prevailed respecting their logical relations; and it was not until the publication 1821 of the "Natural History of the *Crinoidea*," by . Miller, a German naturalist residing in Bristol, that successful attempt was made to systematise the up, by showing the true relation of its diversified ns to each other and to existing types. Miller was le enough to recognise the close resemblance in the leton of the Liassic Crinoids first differentiated him as *Pentacrini*—not only to that of a stalked noid still living in the West Indian seas (which he cribed under the name of *Pentacrinus caput Medusæ*), also to the unstalked *Comatula* of our own shores, ch had been previously ranked with *Euryale* as an ıluriid; and taking this as his point of departure, he ked out the morphology of the other fossil Crinoids known, with a success which has rendered his ıograph the foundation of all that has been since done the systematic arrangement of the multitudinous ject forms which palæontological research is continu- bringing to light. His recognition of the Crinoidal acter of *Comatula* was afterwards fully confirmed by discovery, made in 1836 by Mr. J. V. Thompson of k, that *Comatula* passes the earlier part of its life in attached condition as a Pentacrinoid; dropping off tem at a certain stage of its growth, and thenceforth aining free.

ne "epoch-making" monograph of J. S. Miller was followed in 1834 by the now classical Memoir of Joh. Müller, of Berlin, "Ueber den Bau des *Pentacrinus caput Medusæ*"; of which recent type the soft parts were then for the first time described. The material for this description was chiefly furnished by a single spirit-specimen of the West Indian *Pentacrinus;* but as this wanted its visceral mass, the description of that part was supplied from *Comatula*, the structure of whose arms and ventral disk was found to conform very closely to that of the same parts in *Pentacrinus*. Müller completely reformed the nomenclature of his predecessor; and his designations of the several pieces of the Crinoid skeleton are now adopted by all writers on the group. And as, in addition, he was the first to give an account (although in several respects an erroneous one) of the nutritive and reproductive apparatus of the Crinoids, his memoir constitutes, as it were, the basement-story of the edifice whose foundation had been laid by J. S. Miller.

This was afterwards further built upon by Prof. Wyville Thomson and Dr. W. B. Carpenter; who, seeing that a thorough study of the entire life-history of *Comatula* would be likely to furnish a key to that of the extinct Crinoids, agreed to prosecute it conjointly: the former undertaking the earliest stage, that of the free-swimming pro-embryo (whose existence had been made known by Busch, a pupil of Müller), up to the time of its first attachment by a calcareous stem; and the latter following the Pentacrinoid through the successive phases of its existence, to its detachment and subsequent full development into the free *Comatula*. The results of their researches, embodied in the successive communications made by them to the Royal Society, have not only shown how these creatures lived and moved, but have furnished (as they anticipated) valuable guidance to all subsequent investigators into the Palæontological history of the *Crinoidea*. And they have also served as the basis of the more minute anatomical inquiries of Ludwig, Greef, Perrier, and Dr. P. Herbert Carpenter; which, prosecuted with every advantage afforded by improved methods of microscopic examination, have confirmed Dr. Carpenter's correction of several serious errors in Müller's anatomy; whilst his important determination, both anatomical and experimental, of the principal nervous system in *Crinoidea*, has been recently put beyond all doubt (though long contested as morphologically impossible) by the further experiments of Prof. A. M. Marshall and Dr. Jickeli (see p. 407 *et seq.* of Dr. P. H. Carpenter's Report).

Prof. G. O. Sars's discovery, in 1864, on a bottom of from 400-500 fathoms' depth, of the singular little stalked *Crinoid* to which he gave the name *Rhizocrinus lofotensis*, was followed by the discovery, in the *Porcupine* Expedition of 1869, of a new and delicate Crinoid belonging to the same family, named *Bathycrinus gracilis* by Wyville Thomson, who brought it up from 2435 fathoms' depth in the East Atlantic; a second species of *Rhizocrinus* being also met with. And in 1870 a fortunate haul made by the *Porcupine* in 500-900 fathoms off the coast of Portugal, brought up twenty specimens of a full-sized new species of *Pentacrinus*, called by Dr. Gwyn Jeffreys (who had charge of that cruise) *P. wyvillie-thomsoni*.

About the same period, the United States Coast Survey

brought up both *Rhizocrinus lofotensis* and the second species, *R. rawsoni*, in the West Indian Seas; while Sir Rawson Rawson, Governor of Barbadoes, who had been interested in the work by Dr. Carpenter, obtained three specimens of the singular genus *Holopus* (previously known as a recent type by only a single specimen so imperfect that its crinoidal nature was doubted), and several *Pentacrini* belonging to species which had been previously obtained for Wyville Thomson by Mr. Damon's collectors in the same region.

This was the sum of our knowledge, alike of types and of localities, when the *Challenger* Expedition set forth in 1872. The collections made during her voyage, supplemented by those made in the West Indian area by the U.S.A. surveying-ship *Blake* (types of which were placed by Prof. A. Agassiz in the hands of Sir Wyville Thomson for description), and a few gatherings from other sources, now raise the total of existing generic forms to 6, and of species to no less than 32; at the same time demonstrating the very wide diffusion of the stalked Crinoids over the oceanic floor, and showing their bathymetric range to extend from depths of less than 100 fathoms to 2500. A large collection was also made by the *Challenger* of unstalked *Comatulidæ*, including the singular aberrant genus *Actinometra*; together with a single specimen (recently described by Dr. P. H. Carpenter[1] under the generic designation *Thaumatocrinus*) of an unstalked type which presents a most singular survival of Palæocrinoidal characters.

Finding, on his return from the *Challenger* Expedition in 1876, that Dr. P. Herbert Carpenter had been further prosecuting the study of the *Comatulidæ*, on the basis laid down by his father, Sir Wyville Thomson placed in his hands the whole *Challenger* collection of unstalked Crinoids, which included not less than 150 new species; keeping in his own charge the collection of stalked Crinoids (together with the types of the *Blake* collection), on which he intended himself to report. This intention, however, he did not live to fulfil; and on his untimely death in March, 1882, Mr Murray requested Dr. P. H. Carpenter to undertake the stalked Crinoids also. Beyond naming (mostly without diagnoses) several new genera and species, and directing the execution of 28 plates, Sir Wyville Thomson had made no preparation whatever for his Report; and on his successor, therefore, almost the whole labour of its production has fallen. The result has fully justified Mr. Murray's selection; for we feel sure that in proportion to the previous knowledge possessed by any student of this Monograph, will be his admiration of the masterly skill with which the knowledge derived from the careful and thorough study of every existing type at present known is made to elucidate the structure and life-history of the extinct Crinoids; this being no less apparent in the case of the *Palæocrinoidea*, which differ most widely from existing forms, than in that of the *Neocrinoidea*, many of which are represented in our existing fauna by forms that differ from them only specifically. In this, his *opus magnum*, will be recognised that combination of a remarkable aptitude for the apprehension of details, with a philosophic grasp of his subject as a whole, by which Dr. P. H. Carpenter's previous contributions to its literature have been distinguished; making him equally at home in [illegible] type, in working out the minutest features of [illegible] tion, and in discussing the homologies of the [illegible] with those of the other divisions of the great Echin[illegible] group. Whilst giving the fullest credit to his predec[illegible] and contemporaries, he has endeavoured to [illegible] every point for himself; frequently closing [illegible] curity, or satisfactorily settling a disputed [illegible] more extended research of his own. And when [illegible] found his own inferences from the study of [illegible] to disagree with those of Palæontologists, [illegible] acquired a deserved reputation for their labours [illegible] fossil Crinoids, he has set *forth* the grounds [illegible] opinions, and his own reasons for dissenting [illegible] with impartial fairness. This is conspicuous in [illegible] cussion of the morphological relations between [illegible] *crinoids* and the *Palæocrinoids*; as to some [illegible] which he is at issue with the highest authority [illegible] latter group, Mr. Charles Wachsmuth, of Burlington, [illegible] U.S., which locality seems its metropolis. "[illegible] approached the subject," he says, "from [illegible] but upon one point we are in complete accord [illegible] the desire to find out the truth."

The *first* division of the Report, extending [illegible] quarto pages, is devoted to the Morphology and [illegible] History of the *Crinoidea* generally, treated [illegible] following heads:—(1) The skeleton, with the [illegible] union of its component joints; (2) the [illegible] appendages; (3) the calyx; (4) the rays; [illegible] mass; (6) the minute anatomy of the [illegible] (7) the habits of recent Crinoids, and their [illegible] the geographical and bathymetrical distribution [illegible] Crinoids; (9) the relation between the [illegible] fossil Neocrinoids; and (10) the relations of [illegible] crinoids to the Palæocrinoids. All these [illegible] treated with a completeness which leaves [illegible] desired; rendering this portion of the work [illegible] able Introduction to the study of the Crinoids [illegible] without a thorough mastery of which no one [illegible] forth be qualified to discuss any portion of the [illegible]

The *second* division commences with a [illegible] the principles on which the Classification of the [illegible] should be based; after which, every type of [illegible] Crinoids at present known is *fully* described, [illegible] tions discussed. A few of the most interesting [illegible] to our previous knowledge will be briefly noted [illegible] samples of their value.

The structure of the strangely aberrant [illegible] which the basal and radial plates are [illegible] losed into an asymmetrical tube-like calyx, [illegible] irregularly-expanded base, while the arms [illegible] ally massive—is elucidated as fully by the [illegible] specimens permitted; and it is shown that [illegible] Cretaceous *Cyathidium*, with the Lias[illegible] *Eudesicrinus*, which had been previously [illegible] family *Holopidæ*, but also the Upper [illegible] *crinus* of Hall, are to be associated with [illegible] pedigree of this family seems more assured [illegible] any other recent type at present known.

The new genus *Hyocrinus*, mentioned by [illegible] Thomson for a beautiful little deep-sea [illegible] superficial resemblance to *Rhizocrinus*, [illegible] P. H. Carpenter to have characters [illegible]

[1] *Philosophical Transactions*, 1882, p. 905, and "Report," p. 320.

as to require being ranked as a type of a new family, , while not specially related to any other Neo- d, presents important characters that connect it the Palæocrinoids.

s *Bathycrinus* of Wyville Thomson, of which three s are now known, and the *Rhizocrinus* of Sars, of the two species now known prove to have a wide geo- ical distribution, are next minutely described as mem- f the family *Rhizocrinidæ* (De Loriol). This family ented in the Cretaceous and Tertiary epochs the more highly developed *Apiocrinidæ* of the Jurassic ; ere seems every probability that we can now con- reconstruct the whole anatomy of the Pear En- s on the basis supplied by Ludwig's study of the soft of *Rhizocrinus*, and Dr. P. H. Carpenter's account se of *Bathycrinus*.

next come to *Pentacrinus*, the typical genus of the *Pentacrinidæ*, as this is the typical family of the *inidea*. Every palæontologist is familiar with the rdinary development of this family type in the c period, as shown in the splendid slabs exhibited r museums. The most remarkable species, as s the length of its stem and the number of the nent joints, is *Extracrinus subangularis* ; fossil ens of whose stem have been found to measure o to 70 feet. The mode in which the new joints ded at the summit of this stem was studied by tedt, as well as the fossilised condition of his speci- ermitted ; but Dr. W. B. Carpenter has been able e it out more completely in the recent *Pentacrinus -Thomsoni* ; and the excellent figures drawn by Mr. West for the illustration of a monograph of that hich Dr. Carpenter formerly intended to produce, very successive stage in the development of the nts intercalated at and near the summit of the stem, adial assumption by the intercalated segments of aracters of those with which they alternate, and the sive change from a pentangular to a circular out- well as in their articulating surfaces, which both inally undergo ; thus making it clear that great care e used in erecting new fossil species (as has been tly done) upon the slender evidence of an inch or stem.

he genus *Pentacrinus*, the three species which had btained from West Indian Seas before the dis- of the European type, had been so variously and so diversely described, that their synonymy in a state of hopeless entanglement. By a careful ison, however, of the best-authenticated specimens with the large number since collected, Dr. P. H. ter has found himself able to clear up the con- this having partly arisen from the wide range of ual variation, especially in a character hitherto d as of fundamental importance—the completeness asal circlet, and its external conspicuousness, as in the number of arms to each ray. The first species, originally called *Isis asterias* by Linnæus, ves to be the rarest ; several of the Museum speci- hich had been referred to it, being here shown to to the species first distinguished by Œrsted in *P. müllcri*. Greatly exceeding both these in ce, is the elegant species originally named *P.* in 1864 by Wyville Thomson, who had obtained a specimen of it from Mr. Dumon ; the dredgings of the U.S.A. steamer *Blake* in the Caribbean Sea and the Gulf Stream Channel having brought it up *by the hundred*, so that, as Prof. Agassiz remarks, "we must have swept over actual forests of Pentacrini crowded together, much as we find the fossil Pentacrini on slabs." Another species, *P. blakei*, was dredged by the *Blake* at four stations in the Caribbean Sea ; and neither of these four species has been met with elsewhere. Of the *P. wyville-thomsoni*, which first presented itself in the *Porcupine* dredging of 1870, thirty specimens were recently dredged by the *Talisman* (French) at a depth of 800 fathoms off Rochefort ; but it was not anywhere met with by the *Challenger*, which, however, brought up a specimen of a beautiful new species, *P. macleayanus*, from the Tropical Atlantic, several specimens of two types respectively named *P. nareianus* and *P. alternicirrus*, from the Western Pacific, and a single mutilated specimen from the Japan Sea of a doubtful type, which, on account of the deficiency of calcareous material in its calyx, Dr. P. H. Carpenter provisionally names *P. mollis*. All these species appear to have but a limited geographical range ; and this seems also to have been the case with the fossil species of the Lias, the British and Continental species being mostly different. These, too, have a limited geological range ; no species occurring in all its three divisions, and only two out of the fifteen which are found in the middle and upper Lias of this country being common to those two divisions.

Of all the stalked Crinoids, it is *Pentacrinus* (as was seen by J. S. Miller) which bears the closest resemblance to the unattached *Comatula* ; the chief difference being that the basals of the pentacrinoid larva are retained in the adult *Pentacrinus*, whilst they disappear externally in *Comatula*, inward prolongations of them coalescing to form the curious "rosette" first described by Dr. W. B. Carpenter. In regard to their mode of life, there seems really very little difference between these two types ; for observation of the habits of living *Comatulæ* shows that they only perform their beautiful swimming movements in order to find a suitable base to which they can attach themselves by their dorsal cirri ; whilst on the other hand it seems quite certain that the stalked *Pentacrini* are not unfrequently detached by the fracture of their stems just below one of its nodal joints, and that the cirri which spring from the latter then bend downwards and cling to any suitable attachment, just like the dorsal cirrhi of *Comatula*. The structure of the visceral disk as well as of the arms and pinnules of *Pentacrinus*, has been found by Dr. P. H. Carpenter to bear the closest similarity to that of the corresponding parts in *Comatula* ; and while the five-chambered organ at the base of the calyx, from the walls of which the primary nerve-trunks radiate, is much smaller in *Pentacrinus* than in *Comatula* (its greater size in the latter being obviously related to the number of verticils of cirral nerve-cords it has to give off), a similar dilatation of the Crinoidal axis presents itself in each node of the stem, giving off from its exterior a single such verticil.

It is not a little curious that in the Eastern Archipelago and the neighbouring part of the Pacific, *Pentacrinus* is replaced by a new generic type, closely allied to it in the most essential features of its structure, in which Sir

Wyville Thomson assigned the name *Metacrinus*, though without defining its distinctive characters. No fewer than eleven species of this genus were dredged by the *Challenger*; and, previously to his receiving this collection, Dr. P. H. Carpenter had come to the knowledge of three other species, a description of which he has communicated to the Linnæan Society. All these seem very limited in their geographical range, and not one of them has been found in the Atlantic. No fossil representative of this genus is at present known; but it is by no means impossible that some of the Liassic (reputed) *Pentacrini* may prove to belong to it.

In addition to the 28 plates drawn for Sir Wyville Thomson, and 5 of *Pentacrinus wyville-thomsonii* supplied by Dr. W. B. Carpenter, 35 plates have been drawn under Dr. P. H. Carpenter's direction, many of them containing numerous figures; while another has been autotyped from micro-photographs prepared by himself; making a total of 69 plates, for the most part admirably executed, besides 21 woodcuts in the text. When we add that the work is provided with a copious bibliography and an excellent index, we hope that we shall have made it clear that nothing, in our judgment, is wanting to its completeness.—The report on the *Comatulidæ*, of which the preparation was far advanced before it was put aside for that on the stalked Crinoids, will, we trust, speedily follow. We shall next look for the monograph of the *Blastoidea*, on which, it is understood, Dr. P. H. Carpenter has been for some time engaged, in conjunction with Mr. R. Etheredge, jun., and which will, we believe, throw an altogether new light on that most interesting group. And every British Palæontologist, we feel sure, will desire that he may then find himself enabled to undertake, on the sure basis he has now laid, a complete review of the Fossil *Crinoidea* and a re-investigation of the little-understood *Cystidea*.

FRANKLAND AND JAPP'S INORGANIC CHEMISTRY

Inorganic Chemistry. By Edward Frankland, Ph.D., D.C.L., LL.D., F.R.S., Professor of Chemistry in the Normal School of Science; and Francis R. Japp, M.A., Ph.D., F.I.C., Assistant Professor of Chemistry in the Normal School of Science. (London: J. and A. Churchill, 1884.)

WHEN one opens a new book on Chemistry written by men who are generally recognised to be masters of their subject, one expects to find some light thrown on the great and confused heap of details with which one is accustomed to be confronted in the pages of the ordinary chemical text-book.

Hydrogen, it is true, can scarcely be expected to have changed its properties since the last treatise on descriptive chemistry was published; it still remains "a colourless gas devoid of taste and smell"; it is still a fact that "owing to its lightness this gas may be collected in inverted vessels by upward displacement." No one will venture to dispute the assertions that "in the free state hydrogen occurs in the gases of volcanoes (Bunsen)," or that "in combination hydrogen occurs in enormous quantities in water." But we have heard these statements so very often. Are they not preserved for us in the pages of scores of books, and of [illegible] pamphlets? Surely it is not asking too much [illegible] masters in chemistry that they should begin [illegible] some use of the many facts which have been [illegible] collected. The "hewers of wood and drawers of [illegible] have brought the materials into the camp; now [illegible] there for ever unused? They have been actually [illegible] catalogued a thousand times; was it necessary [illegible] aneous that Profs. Frankland and Japp should [illegible] the work of issuing another catalogue?

The book before us contains 783 pages [illegible] matter; of these, 650 pages are devoted to [illegible] of the elements and their compounds. One [illegible] much in this part of the book, except a repetition [illegible] well-known facts. The formulæ in this book are [illegible] a little more picturesque than usual; the judicious [illegible] ployment of thick type and small *p's*, whether [illegible] able or not from the chemical point of view, [illegible] gives an air of distinction to the page which the [illegible] text-book is obliged to do without.

Turning to the introductory chapters, one is [illegible] taken aback to learn on page 1 that cohesion, [illegible] gravity, chemical affinity, and electricity, are all [illegible] force. After learning this, one is certainly not [illegible] to be informed (pp. 64–5) that the formulæ H–H

and O=C=O, "give no indication that the molecule [illegible] first compound contains a vast store of force, [illegible] last is, comparatively, a powerless molecule." The [illegible] fusion between force and energy is pointed out [illegible] throughout the book. Is there something [illegible] absurd in the attempt to apply dynamical [illegible] chemistry? If not, why is it that when a chemist [illegible] himself to a statement involving the conception [illegible] and energy in nine cases out of ten he gets [illegible] confused?

A great part of the advance made in chemistry [illegible] recent years is based on the adoption of [illegible] practical definitions of the atom and the molecule, [illegible] on the conceptions which flow from these definitions. [illegible] Chapters IV., V., and VI. of Profs. Frankland and Japp's [illegible] book deal with these subjects. Chapter IV. gives a [illegible] and trustworthy account of the laws of chemical [illegible] nation; Chapter V. deals with the atomic theory [illegible] exceedingly satisfactory manner; and Chapter VI. [illegible] sents us with a sketch of the methods whereby [illegible] molecular weights of gaseous elements and compounds [illegible] and the atomic weights of elements are [illegible] These chapters appear to us to be expositions [illegible] careful study of them is likely to be of much [illegible] the student of chemistry. But if the reader be [illegible] critical turn of mind, he may object that he [illegible] shown the "steep and thorny way," while the [illegible] themselves, in the other parts of their book, [illegible] path of dalliance" tread. Thus, to take an [illegible] molecular formula of ferric hydrate is given [illegible] as $Fe_2H_6O_6$; but ferric hydrate has never been [illegible] and the theory of molecules as described in Chapter [illegible] is a theory strictly applicable to gases only. [illegible] might object to the incongruity between the [illegible] Chapters V. and VI., and the practical [illegible] book. These chapters define [illegible]

ve us the outlines of a self-consistent theory; but the apters on descriptive chemistry employ the term "mole-le" in the vaguest and widest way, *e.g.* (p. 67) these rmulæ are given as molecular $(KO)_2$, (O_2Zn), $(NH_3)_2$, d these as semimolecular OK, $\left\{\begin{matrix}O\\Zn,\\O\end{matrix}\right.$ NH_3.

Indeed, all through the book little or no distinction is ıde between the formulæ of gases and those of solids; are treated as molecular. The disadvantage of doing s becomes very apparent when we turn to our authors' atment of the much-vexed questions connoted by the m "valency" or "atomicity."

Here the reviewer would protest against the use the term "atomicity" as synonymous with "valency atoms." On p. 30 we are told that the molecules hydrogen, oxygen, chlorine, &c., are diatomic, and molecule of ozone is triatomic; if, therefore, we et with the statement that oxygen is a diatomic ment, we should naturally interpret this to mean t the molecule of oxygen is twice as heavy as atom; but we find that it means something quite erent: it means, according to this book, that oxygen an atom-fixing power equal to twice that of one atom ıydrogen.

he treatment of valency, or equivalency, of atoms by fs. Frankland and Japp is, in our opinion, open to the vest objections.

he statement on p. 57 that the atomic weight of an nent "is the smallest proportion by weight in which that nent enters into, or is expelled from, *a chemical com-nd*" (italics are ours), we think, strikes the keynote of confusion which immediately becomes evident. If for words in italics are substituted the words, *a molecule chemical compound*, and if the definition of molecule, given by Clerk Maxwell or other physicists and as tically adopted by our authors (pp. 26–7), is rigidly ered to, the confusion, we are convinced, would sh.

may be said that the word 'molecule' is understood he definition quoted, and also in the statements that ear on p. 57 and elsewhere—*e.g.* in the mutual action inc and steam, "one atom of zinc expels *from the* two atoms of hydrogen" (italics are again ours); but requent reiteration of the word would do something strain the chemical student from giving the reins to ancy and plunging into dreams of graphic formulæ osed to represent the structure of molecules, the ence of which is unproved.

ıch element is said (p. 58) to have a certain atom-g power, and we are told "each unit of atom-fixing r will be named a bond." But when we come to the formulæ which are constructed on this basis, we hat a bond is not a unit of atom-fixing power or of ther "power" at all. We find that an element with onds is simply an element one atom of which usually ines with two atoms of hydrogen or chlorine, &c., he "power" cannot be measured by the number of [redacted] in our opinion altogether erroneous to [redacted] of power, unless one is pre-[redacted]" in a sense in which no [redacted] to use it, and the [redacted]

The valency of many elementary atoms varies according to the nature of the other atoms with which they are combined in various compound molecules. The valency of an atom is, as a rule, expressed by an odd or an even number (there are more exceptions to this rule than the authors seem willing to admit on p. 60). "These remarkable facts can be explained by a very simple and obvious assumption, viz. that *one or more pairs of bonds belonging to the atom of an element can unite and, having saturated each other, become, as it were, latent.*"

One is obliged to ask here, Is this a scientific explanation? Does the explanation explain anything? What are these bonds which "become, as it were, latent"? Are not the facts much more "simple and obvious" than the explanation? What is the explanation?

Then we are told (p. 61) that "the apparent exception to this hypothesis [one asks, What hypothesis?] nearly all disappear on investigation. Thus, iron, which is a dyad in ferrous compounds as $(FeCl_2)$, a tetrad in iron pyrites (FeS_2), and a hexad in ferric acid $(FeO_2(OH)_2)$, is apparently a triad in ferric chloride $(FeCl_3)$; but the vapour-density of ferric chloride shows that its formula must be doubled—that, in fact, the two atoms of the hypothetical molecule of iron (Fe_2) have not been completely separated." Then follow structural formulæ (so called) of the iron compounds already named. If this is the kind of explanation that the bond hypothesis has to give of facts, we may well doubt whether any scientific advance is to be hoped for by using this hypothesis.

There is, it would seem, something metaphorical in the statement that when the bonds have satisfied each other they "become, *as it were*, latent" (italics ours): and "when a metaphor comes to be regarded as an argument, what an irresistible argument it always seems"!

One is so apt in chemistry to prove a fact by a hypothesis. We cannot but think that this method is too often followed in the book before us. For instance, the fact that water of crystallisation is generally easily removed by heating the crystalline salt, is explained (?) by the statement that "in the formation of such compounds no change takes place in the active atomicity of any of the molecules."

Great advances have been lately made in the study of chemical affinity. We turn with pleasure to Chapter XII., hoping to have our views on this subject rendered clear and definite.

Chemical affinity "may be measured as regards its *extent* and as regards its *intensity*." Relative extent of affinity is measured, we are told, by the number of atoms of a standard element with which two or more given elements (? elementary atoms) can combine. "*Extent of affinity* is thus directly connected with *atomicity*." "*Relative intensity of affinity* of two or more elements for any given element refers to the resistance which their compounds with this element offer to decomposition. The measure of this intensity is the quantity of heat evolved in combination or required for decomposition."

"Extent of affinity" seems to be here closely connected with the atom of the elements; we are left in doubt whether "intensity of affinity" is or is not similarly connected with these atoms.

The measure of the intensity of affinity seems to have something of the nature of an atomic bond, it is so very

protean; our faith in this measure is rudely shaken by the statements on pp. 104-5. There are many interesting statements in Chapter XII., but one finds it difficult to discover why the heading should be "Chemical Affinity."

The time is surely past when we are to expect the chemical student to be content with a sketchy outline of such subjects as affinity and thermo-chemistry. If these subjects are really parts of the science of chemistry—and surely they are all-important parts—let them be dealt with as such, and not thrust into a corner and treated so that the student is ready to conclude that, if he is able to repeat the properties of the elements and their compounds, he must of necessity be a chemist. The real science of chemistry is something more than a string of disconnected facts and a few mutually independent hypotheses.

We cannot but think that, had the authors of this book cut out most of the graphic formulæ, been content to use the notation adopted by other chemists, and carefully considered, digested, and arranged the materials they have brought together in the first nineteen chapters, they would have produced a much better and a much more scientific treatise. M. M. P. MUIR

LETTERS TO THE EDITOR

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts. No notice is taken of anonymous communications.

[The Editor urgently requests correspondents to keep their letters as short as possible. The pressure on his space is so great that it is impossible otherwise to insure the appearance even of communications containing interesting and novel facts.]

Mr. Lowne on the Morphology of Insects' Eyes

(1) It is, I imagine, sufficiently obvious that I was not at liberty to state in my previous letter the circumstances connected with the action of the Royal Society in regard to Mr. Lowne's paper, now inextricably related by him.

It is also clearly impossible that I should take any notice of Mr. Lowne's letter in your journal of April 9 (p. 528) beyond expressing my surprise that he should suppose that I have had any personal feeling in regard to him or his work, and my regret that he should accuse Prof. Schäfer, Dr. Hickson, the Royal Society, and the Cambridge histologists of ill-treating him in various ways.

(2) I would beg to assure my friend Dr. Romanes that he is mistaken if he imagines that I intend to publicly discuss the affairs of the Linnean Society with him either here or elsewhere.

At the same time I consider that I am at liberty to express my judgment as to the scientific value of a paper published by the Linnean Society, and that neither he nor the author of the paper are entitled to object to my discharging what I conceive to be my duty in this respect. E. RAY LANKESTER

Abnormal Season in the Niger Delta

As you are aware the waters of the Nile are at present abnormally low, and having just received a letter from the Niger, I thought it might interest you to learn that the season is abnormal also there. My correspondent, who has an experience of many years on the river, states:—

"We have had the most extraordinary weather since the commencement of the year—heaps of rain up to the present during both months (January and February), and yesterday one of the worst tornadoes I have ever seen, and that from the due north; usually the bad ones come about Christmas from the south-east. I never saw rain, up to the present, after Christmas during the first three months of the year, which are the unhealthy ones. These months are this year so far fairly healthy, although the falling of so great a river as the Niger must wash down a mass of filth, not so much from the towns as from the hundred small and large villages and towns on its or tributaries along its banks."

I have asked if any barometer observations are kept could have a return of them for the past year.

AIMS AND METHODS OF THE TEACHING OF PHYSICS[1]

THE United States Bureau of Education employed Prof. Charles K. Wead, A.M., Professor of Physics at the University of draw up a set of inquiries respecting the physics and to collate and discuss the answers The results of his labours are now before unusually lengthy circular issued by the are drawn from seventy replies to a set of to a selection made by the Commissioner of of masters of schools of various grades in States, compared also with information England and other countries. A table as clearly as can be done in a word or two heading the tendency of each answer, and

[1] "Circular of Information," No. 3, 1883, of the Bureau of Education. (Washington, 1884.)

ic points of difference and the correspondents who
e replies seem to show:—

A widely-spreading preference for science over
ture of classics,—(*a*) as training of the mind; inducing
s of observation such as no study of grammar does,
consequently a great increase in what is called
mon sense, which close attentiveness soon spreads to
studies also, giving each observer who has caught
pirit of inquiry and learnt how to observe, compare,
draw conclusions himself, confidence in his own
vations, instead of depending upon the authority of
book. It is well described from the master's point
ew:—

The advantages of the study have been: (1) Wonder-
nickening of the intellect, lively interest in the school;
ubsequent growth into the scientific and scholarly
, developing a wonderful ingenuity in mechanical
vances and the manipulation of tools; (3) doubling
me instances quintupling) the number of boys who
the high school course, and giving many a strong
to industrial pursuits in their better-skilled depart-
s. It has secured students of broader power of
ght and generalisation. It has cultivated the senses
nat pupils were not 'nature-blind.' It has trained to
abit of nice adjustment of probabilities, which has
ed with marked power in giving a critical acumen in
ical research." (p. 16).

nce, therefore, it is our middle and higher classes
have to look to their brains for their success in life
they specially who want this training in scientific
od which will "teach them how to learn, not what to
."

As valuable information—valuable first from a
arian point of view:—

When one reflects how few persons there are who
the composition of a drop of water or a grain of
in comparison with those who are familiar with a
verb or a Greek preposition, and how much each
ese separate classes of educated people is accom-
ing, it seems plain to me that instruction in physics
the utmost importance to our people; for, beyond
oubt, scientific men have done, are doing, and will do
for the advancement and well-being of our country
any other class of her citizens." (p. 50).

d from this same point of view *any* scientific informa-
is valuable to children who leave the elementary
ols early in life, though it is generally urged that
ng them with incoherent facts is a most useless
ation, and that what information is given must,
fore, form part of a scheme for teaching them ob-
ation. The American Association for the Advance-
of Science protests against any way of *giving* them
mation; they must *get* it.

ch information, however, is also rising in value as
ccomplishment, and the lack of it will soon be looked
as an ignorance of classics was a generation ago.
ll be felt that "no knowledge of language can atone
n ignorance of nature," and that a neglected *A* or *a*
quantity is a very venial offence compared with
tering why eclipses never take place when the moon
f full.

That in the lowest schools, lessons on the elements
cience should be given: examples being taken as
r as possible from the most familiar toys and other
cts about them. Experiments with such things are
, because they are a fascination to the young, and a
from committing Latin Grammar to memory. But
desirability of making this instruction the preparation
e higher classes is met by the fact that so few go on to
, and it seems clear that something more exact and
matic should be commenced among those who do go
ther, unless this is done, although a boy may have
ired some general notions of the terms and subject-matter, yet if fundamental points have been neglected in the lower schools, either the college class must be kept back to study these points, or he must build all his advanced work on an uncertain foundation.

(3) A further divergence is found on the question of experiments. A successful experiment is a great power for good, but it is a gift to be able to make experiments accurately and successfully; and, if the experiment fails, the faith in all teaching connected with it is shaken; still less can it be made the basis of fresh conclusions. Imperfect experiments, therefore, are an unmixed mischief, and for elementary classes all should be done by the teacher, who, besides a good general knowledge, should have some manual skill in using or even in making apparatus: "otherwise mistakes in method and fact will be common in his teaching, and his instruction will be a constant appeal to the text-book or other authority, thus losing the very thing that is of peculiar value in the training derived from the study of science." If the higher school students are put to experimenting when unqualified for it, and with inadequate means, habits of slovenly experimenting and inconsequent induction are formed, or the student is disgusted with the unsatisfactory nature of the whole thing.

(4) In the upper grades, however, and among specially gifted boys the value of experiments both by teacher and scholar is insisted upon almost as uniformly as it is among those who study the science of teaching and the teaching of science in England. "No support is given to the notion common among men of a literary education that physics can be learned as history is, by reading a book. Experiments are essential to the study, and to profess to teach physics without providing suitable experiments in sufficient number to illustrate the subject must be considered as a case of false pretences." Learning science by experiments draws out powers of the mind that school-teaching of every other kind, involving as it does unquestioning submission to authority, compulsorily numbs. The exact observation of facts and, on the one hand, the bringing those into relation which had seemed unconnected, and, on the other hand, the loosening of independent facts that wise saws have placed in close relation; in a word, discovery, with its necessary companions, self-reliance, independent thought, shrewdness of judgment—the very qualities which make a successful man of the world—are all developed by experimental science instead of the too frequent opposite effect which makes anxious business fathers dread too much schooling for the sons who will have to follow them.

(5) Parallel to (3) and (4) are the conclusions drawn as to making apparatus. Bad apparatus induces imperfect experiment, and, as laboratory work must be serious and yield visible results or it will be despised, the apparatus for the students' use must not be flimsy, or in the nature of a plaything merely. It is therefore penny wise and pound foolish for a teacher to make his own apparatus. If his time is worth anything his productions will cost more than the more perfect work of an instrument maker; and, besides the great chances of imperfection from the beginning, it will be liable to such faults as warping, and, moreover, not likely to suit the next teacher. On the other hand, such a general rule as this is not intended to tie the hands of gifted teachers who can make everything that comes in their way their slave to answer their questions. There is a rapid descent from such to the plodding worker who teaches for daily bread.

The most difficult question to answer confidently, after taking the opinion of so many doctors, is whether teaching of any use to elementary schools can be made without serious disadvantage to form part of a course pursued further by the higher classes. The Circular finds unanimous agreement among the United States teachers that it is most desirable; and, after quoting English opinions that

our Universities ought to be able to frame such a course, urges that a committee of teachers who have carefully considered the evidence here supplied should be able to draw up a practical scheme sufficiently definite, detailed, elastic, and progressive to secure its wide adoption. Unless this is done, a teacher's work cannot be measured, and he will get neither credit nor cash for it from his judges; and no amount of public opinion will really make such teaching general while this remains so. A good practical suggestion in accordance with these conclusions is that some experienced teacher should devote his power to the preparation of cheap leaflets, not stitched together, for a brief inductive course, from which each teacher might select a series according to his circumstances.

W. ODELL.

THE WORK OF THE U.S. SIGNAL OFFICE UNDER GENERAL HAZEN[1]

THE recent examination by the joint commission of General Hazen and other witnesses, as to the efficiency and economy of the present administration of the Signal Office, is said to have brought out several statements as to the character of the work done by the Weather Bureau, and the progress made by it during the last few years. The following is a brief summary of these, and especially of Prof. Abbe's statement showing the status and work being pursued during the present fiscal year:—

The Signal Service employs 1 chief, 14 second lieutenants, and 500 enlisted men, of whom 150 are sergeants, 50 are corporals, and 220 are privates, but all generally known as Signal Service observers. These 515 persons constitute the Signal Corps proper: but 6 officers detailed from the line of the army are also temporarily attached to the service; and these have control of the disbursements, the property, the weather-predictions, the display of signals, the testing and comparison of instruments, the arctic stations, the international bulletin, the monthly weather review, the Pacific Coast section, and other main divisions of work.

These 6 officers, by the operation of the present laws, are being diminished in number by 2 annually, their places being filled by promotions from among the sergeants of the corps; so that in a few years the service will employ only officers and men of the Signal Corps proper. This elimination of officers who have had from ten to twenty years' experience in the Signal Service and the army is somewhat deprecated by General Hazen, who is very naturally loath to lose their services, while they themselves are loath to go; although it is evident that the corps proper already contains abundant and excellent material for the future needs of the service.

The Signal Service also employs a number of civilians—namely, 2 chief clerks, several clerks of lower classes, and a scientific staff of 3 professors, 4 junior professors, and 1 bibliographer, and a large number of civilian observers, printers, messengers, artisans, &c.—at various points throughout the country. The number of civilian *employées* at the central or Washington office is 64, all of whom give their whole time to the work. The total of those employed at other stations is apparently much greater than this; but each is employed only a short time daily, and most of them receive but 25 cents per day for some one special observation and record. The enlisted men of the service occupy about 200 stations scattered throughout the United States, including Alaska, at an average distance of 200 miles apart. About an equal number of stations are also occupied by civilians, observing the height of water in the rivers, or displaying storm-signals. From about 4500 other civilian observers reports are received gratuitously by mail on weekly or monthly forms. These observers are classified about as follows: voluntary land observers, 270; voluntary [illegible] servers, 480; international observers, 36; [illegible] observers, 18; state weather service, 40; [illegible] observers, 1200; thunderstorm reporters, 2000.

The following are some of the more prominent important steps of progress taken during General [illegible] administration:—

The introduction of consulting specialties and [illegible] experts in the available working force of the office; assignment of selected sergeants and private[s] demanding a higher education and special [illegible] investigation or study; the organised study of [illegible] thunderstorms, atmospheric electricity, and other important novel fields of meteorological study; [illegible] duction of weather-signals upon railroad-trains [illegible] benefit of the farmers, and of local town-signals [illegible] benefit of each community; the establishment of severe rules for the verification of predictions [illegible] 85 per cent. claimed at present means much more [illegible] did a few years ago: the enlistment of a higher [illegible] men, the improvement of the courses of instruction men and officers, the compilation of a working [illegible] the literature of meteorology and the signal-office; the organisation of new divisions in the office, [illegible] of the study-room, the physical laboratory, the [illegible] division, and the examiner's division; the publication a monthly summary of international simultaneous [illegible] servation, with a weather-chart showing especially storms on the Atlantic and Pacific Oceans that [illegible] United States; the special study of atmospheric [illegible] with a view to improved methods of determining [illegible] factor; the special study of the exposure of thermometers and correct methods for determining the temperature of the air; the maintenance of two polar and [illegible] auxiliary stations in pursuance of an international [illegible] for the study of the meteorology of the Polar regions; adoption of many of the recommendations of the European International Meteorological Congresses looking to [illegible] formity of methods throughout the world; the study of improved methods of reducing barometric observations to sea-level; the stimulus given to the formation of [illegible] Weather Services (this great advance has been largely due to Gen. Hazen, who has not hesitated to declare himself in favour of co-operation, and not monopoly); [illegible] circulars and assistance over fifteen States have been [illegible] to develop minute internal systems for the study of local climate and the dissemination of weather predictions); the stimulus given to higher scientific work by members of the Signal Service, by requiring [illegible] publishing professional papers, signal-notes, [illegible] &c.; the addition to the Signal Office of a few experts in scientific matters, who are responsible for the proper conduct of work requiring special study; the establishment of a high class of standard instruments, and accurate methods for testing-apparatus furnished to the stations, thus assuring against any deterioration in the accuracy of the work through many years to come; the encouragement and co-operation in scientific work, beyond meteorology, by outside parties, such as specialists in the study of solar heat and atmospheric absorption; the prosecution of balloon-voyages; the adoption of a uniform standard of time for all observers; the [illegible] of a uniform standard of gravity for barometric [illegible] tions; the introduction of new special cautionary [illegible] for high north-west winds and cold waves; the [illegible] of signal-service stations in Alaska for the prediction of storms that strike the Pacific coast, and are followed by the severe cold waves from Manitoba.

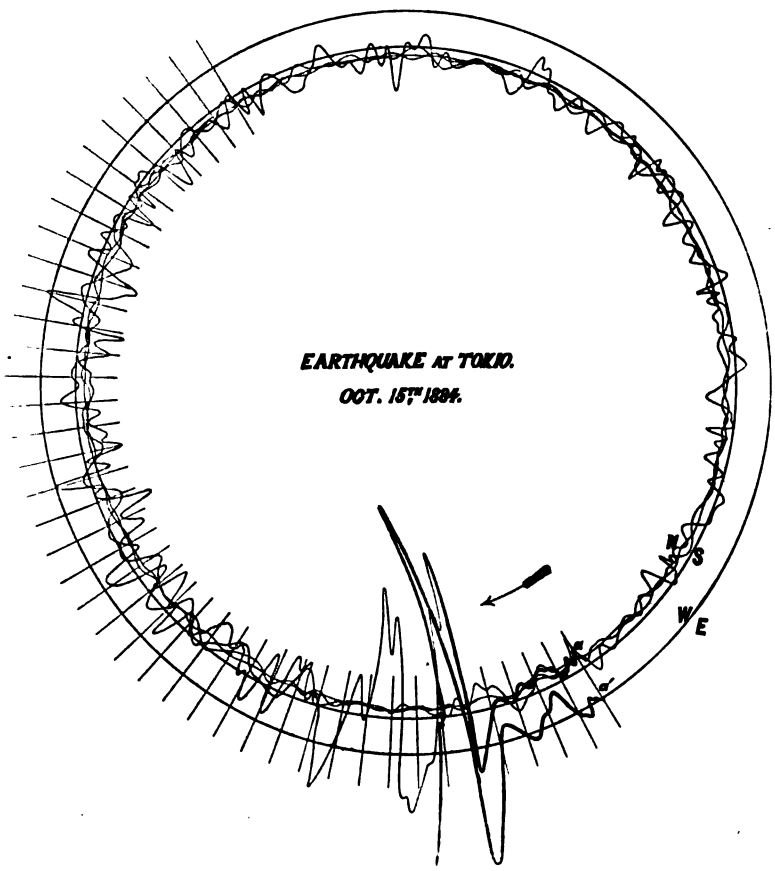
In the prosecution of these and other [illegible] labours the signal-service certainly demands a high degree of organisation, discipline, and intelligence. It is by no means clear that this can be obtained in better way than by a proper combination of [illegible] civilian observers and scientific men.

[1] From *Science*.

A RECENT JAPANESE EARTHQUAKE

AN unusually great earthquake was felt in and about Tokio on October 15, 1884. The annexed autographic record of it comes, with the following particulars, from my former assistant, Mr. K. Sekiya, who is now in charge of the seismological observatory of the University of Tokio. It was given by a horizontal pendulum seismograph of the kind recently described in NATURE (vol. xxx. p. 150), and it has many features in common with the examples of records shown on pp. 174 and 176 of the same volume. But in the present case the amplitude of the earth's horizontal movement far exceeds anything that has been recorded since observations of this kind were instituted in 1880.

The figure shows the record reduced to about one-third its actual size. The undulations on the inner circle have been traced by a pointer which registered the north to south component of motion, and those on the other circle by another pointer, which registered east to west motion. The pointers are prolongations of horizontal pendulums,[1] and trace their records on a revolving sheet of smoked glass, which in this example was started into motion by the earthquake itself, through the agency of a delicate electric contact-maker. The plate is driven by a clockwork train which, after starting, quickly reaches a steady rate under the control of a fluid friction governor. The speed of rotation was one revolution in 82 seconds; the short radial lines mark seconds during the first part of the disturbance. The record on the outer, or east to west circle, has been turned round so as to bring it into synchronism with the inner or north to south record, and the earliest motions are distinguished, in the cut, by the use of a somewhat heavy line. The records begin at *a* and *a'*



and are traced in the direction of the arrow, which is opposite to the direction of motion of the glass plate. At *b* the east to west record comes to an abrupt stop, owing to the displacement there having been so great as to carry that pointer off the plate altogether. The inner record extends over nearly four complete revolutions, showing that visible motions of the ground lasted for about five minutes. During the first half-dozen seconds, while both components were being registered, there is a tolerably close agreement of phase between the two, showing that the displacements were then not very far from rectilinear. The greatest motion in this part of the disturbance took place five seconds fro[illegible]; at that point the actual motion of the gro[illegible]tres from east to west and 2·2 centi[illegible]. [The displacement of the gr[illegible] in the original record, or about one and a third times in the reduced copy given here.] The two components taken together represent a movement of the ground, from one side to the other, of no less than 4·3 *centimetres*—a quantity which is in striking contrast to the "5 or even 7 *millimetres*" which, after three years' experience, I named as the amplitude to which in a Yedo earthquake the displacement from the mean position "occasionally rises" (vol. xxx. p. 175). So far as can be judged from the north to south component alone, the most violent motions were over in about ten seconds, but for some minutes afterwards the oscillations, though very much reduced, continued to exceed in amplitude almost any that I have recorded.

[1] See "Measuring Earthquakes" (NATURE, vol. xxx. p. 150), or a "Memoir on Earthquake Measurement" (Tokio, 1883, p. 22).

Fortunately, however, this earthquake was prevented from being excessively destructive by the unusual slowness of the oscillations. The period of the principal movements appears to have been not far short of two seconds. For a rough estimate of the greatest velocity and acceleration we may treat the 4·3 centimetres movement as simply harmonic, and we find for the greatest velocity 6·8 centimetres per second, and for the greatest acceleration 21 centimetres per second per second, or $\frac{1}{47}$ of g. If the amplitude of motion which was recorded here had occurred in conjunction with the more usual period of three-quarters of a second or so, the destruction would have been immense. The earthquake appears to have been felt over an area of about 20,000 square miles.

Mr. Sekiya writes:—"We are going to exhibit your seismograph in the Exhibition in London, to be held next May. I am sure we will get a first prize medal!" Whether Mr. Sekiya and the Tokio University authorities get their medal or not they should at least excite the admiration of readers of NATURE for the zeal and success with which they are pursuing the study of seismology.

University College, Dundee J. A. EWING

EARLY MATURITY OF LIVE STOCK

THE subject of the "Early Maturity of Live Stock" is, no doubt, bucolical in some of its aspects; but, like many other agricultural questions, it is of great national importance, and is closely related to scientific investigations of much interest. The age at which the live stock of the farm becomes sufficiently mature has been considerably reduced during the past hundred years, both by improved methods of feeding, and still more by the altered habit of the breeds of animals—that is, by their earlier maturity induced by the modern system of breeding. Most persons are aware that the "improved shorthorns" were the artificial creation of two eminent breeders, the Messrs. Colling; that the "improved longhorn" cattle and Leicester sheep were the result of skilful selection and inter-breeding by Mr. Bakewell; and that Mr. Ellman conducted similar "improvements" on the Southdown breed of sheep. All these operations upon the earlier types of animals were initiated in the last century, and they were so successful, from a practical point of view, that both bulls and rams were raised in price from about 5*l.* to 20*l.* respectively to 1000 guineas for single animals of high character and esteemed pedigree in the flocks and herds of Colling and Bakewell.

Other breeders have applied the same arts, and especially the principle of selection, to some of the other breeds, and their object has been earlier maturity. It is obvious that a farmer must adopt that course of feeding which is most economical, and as a certain amount of food is consumed every day by an animal for respiratory and other vital functions, it is evident that the sooner it is fit for the butcher the less total amount of food it will consume wastefully. In the manufacture of meat the food required by an animal for its own purposes may be regarded as waste; so that the importance of saving time in the process of fattening is evident. It is said, indeed, that one-half of the food given to an animal under ordinary circumstances is required for the support of life, and, if that calculation be correct, then a slow-maturing ox, or sheep, at four years old will have consumed twice as much food to produce the same weight as an animal of improved breed at two years old. The period of youth is the period of growth, when the muscles, bones, and other parts are in process of formation, and when the waste of food is necessarily less than it must be at a later period of life. For the sake of economy all animals should be fattened and finished when young, and therefore the question of "early maturity" involves an inquiry into the period of life when the domesticated animals [illegible] in their full maturity and development.

Prof. Low, in his "Domesticated Animals," and [illegible] Youatt, the famous specialist, state that the[y] are [illegible] in a state of nature attained complete maturity [at] four to five years old, their permanent [illegible] complete. This was the stage they had reached [illegible] hundred years ago, when the country was covered [with] woods and wastes, before the great inclosures, and [before] the turnip became a field-crop. Stall-feeding [had] been introduced at that period, and summer [feeding] the marshes and natural pastures, was the only [method] was, for winter use, invariably salted. The [scanty] der of those days retarded maturity and [prolonged] usual period of producing young by more [than] compared with the present time. At this [stage] breeders took up their several subjects with [remarkable] marked, and, it may be added, so remarkable [that] a few generations the complete maturity [both] and cattle—except in regard to the permanent [teeth] been reached in three years instead of four. [The] of three-year-old mutton had now been [reached], some persons perhaps may still remember [having] their youth; and, if so, they must be aware that it [was] no longer. In our own experience we must [confess] have found old mutton rather tough, and, while [admitting] that "the grapes are sour," we see no reason [why] beef and mutton should be superior to old geese [and] poultry, or old game. But, however this may be, [the] perseverance of modern agriculturists and the [competition] of Australia and America in our meat-markets [have] led to still further reductions in the ages at which [animals] are slaughtered.

The action of our leading agricultural societies [shows] that some very recent movements have taken place [with] the purpose of stimulating breeders and feeders [to] saving of still more food and time by early maturity. There must be a limit in these matters. Sheep [and cattle] of massive build are less ephemeral than some [others], and a certain amount of time must always be [required] by them before their periods of complete development and of reproduction of the species can be reached. In 1875, however, the Smithfield Club offered prizes for lambs, having previously confined their favours to [those] one year older at least. There is no rule without [exception], and one particular breed of sheep has been [developed] by arts and wiles, and, for the sake of "Christmas [joints]" to produce its offspring in November, and to [breed] permanently. Usually lambs appear in spring; the "[Christmas] show" is held in December, and lambs at nine [or ten] months old are now expected to exhibit themselves as sheep of great weight. They have responded to the call in the most wonderful manner; they have not only numbered the other "sheep" in the show, but they secured the champion prize for the best sheep [in the] well as the year before, and their weights have [exceeded] those of the old sheep of other days, *i.e.* 16 and [18] field stone (8 lbs.), or 3½ lbs. of mutton per week [from] birth!

Cattle under two years old were first admitted [to the] and their achievements, too, have been astonishing. Early maturity, in short, has reached a new and unexpected stage. It has certainly been hastened, and [animals] are now as fit for slaughter at two years old as they formerly at twice that age. It is worthy of note, from a scientific point of view, that the period of complete [development], as it occurs in a state of nature, has not been [shortened] if at all, altered. It is true that Mr. Reginald, the [present] scientist, discovered a bull at a cattle fair in Paris [in] 1846 with all the permanent teeth fully developed. He was led to investigate the effects of careful breeding and feeding in occasioning that precocious development which has been already described, and this, he says, "cannot be confined to any particular organs. If every one has not equally participated in it, at least there [is] none [that] is not affected by it. Above all, the digestive [system]

d on to play an important part in producing such an ode for early development, since all must essentially t from the nature and action of alimentation, must be of the first to undergo modifications."

e do not question this conclusion, but the teeth and s seem at present to have been slightly influenced by "improvements" we have been considering. It is that the art of breeding can greatly modify the s; it can, in fact, obliterate them in horned cattle, produce them in the hornless breeds, but this is quite t from early maturity, which does not necessarily ify to any great extent, or with any certainty, either the s or the teeth. Occasional examples of a very early de- pment of the teeth, such as M. Regnault describes, do etimes occur, but they are so rare as to be regarded normal, and the rule, with the improved as with the breeds of cattle, is that they produce two permanent at two years old, and two others each year till they ive years old, when they are, as farmers say, "full- thed." It is not improbable, however, that the not unfrequent appearance of the first permanent teeth ss than two years old, as well as the irregular denti- of highly-bred pigs, are manifestations that further future changes may still be anticipated. Among y useful agricultural pamphlets that have been issued the office of *The Field*, it is stated that one will ar shortly on "The Early Maturity of Live Stock."

H. E.

THE BORNEO COAL-FIELDS

AVING recently visited some of the coal-fields in the Island of Borneo, it may be interesting to your ers to know the result. The subject was one of al interest to me, and its investigation was one of rincipal objects I proposed to myself in my travels e East. Just before leaving Australia I had published e *Proceedings* of the Linnean Society of New South s a complete history of the known coal flora of alia, and a review of its geological position. The on of the Australian to the Indian coal flora is well n. It seemed hardly possible that in Borneo, where extensive coal-formations exist, but that some con- ng link would be found between Australia and e subject is very little known. The late Mr. Motley he management of the Labuan Mines. His are the writings on the age of the Borneo coal which are n to me. What he wrote is quoted by Mr. Wallace s work on "Australasia." He regarded the beds as ary, and the fossils as of species of plants and marine ists now living on the coast. He speaks of cocoa- and the peculiar winged seeds of *Dipterocarpus* (so mon in Borneo) being common also in the coal at an. He thought that the beds evidently originated e most recent times from masses of drift-wood ght down by the rivers and stranded on the coast, in ay the traveller sees so often repeated on the Borneo at the present day. He also stated that the Labuan was not, properly speaking, coal, but more like drift- partially bituminised.

. Motley subsequently was killed by the natives at ermassim. It is now six or seven years since the s at Labuan have been worked. I am not sure that ld the same impressions about the South Borneo as of the Labuan beds, but I think I am not far out inking that he regarded all Borneo coal-beds as ging to one immense Tertiary formation.

ere are few countries of the world, except, perhaps, ern Australia, where coal is so extensively developed Borneo. Thick seams crop out in innumerable s on the coast and on the banks of the rivers. In of the streams of North Borneo I have seen water-worn and rounded fragments of coal forming the entire shingle bed of the channel. In some places, again, there are outcrops with seams of good coal 26 feet thick. The coal-formation is the one prevailing rock of the coast. It forms the principal outcrop about Sarawak. At Labuan, also, no other rock can be seen. Lining the banks of the Brunei River, I only saw picturesque hills of very old Carboniferous shale. All the grand scenery of the entrance to the port of Gaya is made up of escarpment of coal-rocks. At Kirdat it is the same, and so I might go on with a long list of coal-bearing localities.

Now, in such a large island as Borneo, with such a wondrous mountain system, it would be absurd to suppose that all this coal belonged to one age. We might as well suppose the same of the comparatively small islands of Great Britain, and yet what an error that would be. In Eastern Australia and in Tasmania, beds of coal of very different age lie close together. I have found the same in Borneo. Whether there is Tertiary coal or not in the island, I cannot say; but there is Mesozoic coal, and probably Palæozoic coal, and coals like those of Newcastle in Australia, whose position hovers between the true Palæozoic and the Trias. To begin with Labuan; the works there have been long since abandoned; the adits are partly filled with water, and the shafts have fallen in, so that it is next to impossible to explore the mine now. But there is plenty of coal and shale on the surface, and there are excellent sections on the sea-cliffs close by. The formation is a drifted sandstone with much false bedding. It contains not a trace of lime or any marine organism. Under the microscope the siliceous grains are seen to be rounded. I think it is an Eolian formation with lines of rounded pebbles of small size. The whole deposit is very similar to the Hawkesbury sandstone of Australia, which is of Oolitic age. In both formations there are roots and carbonised fragments of coniferous wood, in which the tissue is still to be traced. The coal on the surface is a truly bituminised coal, very brittle, and like what we get in the same rocks in Australia. The few plant-remains I saw were not referable to any known genus; they were like Zygophyllites, and perhaps these are the plants which have been identified as wings of *Dipterocarpus*, which they remotely resemble.

I saw no marine fossil, and the absence of any lime in the beds makes one think that those which were discovered did not come from any of the strata which are exposed in section. Sir Hugh Low, who resided many years at Labuan, gave me some casts of marine fossils taken from the locality. They were casts not easily identified, and certainly not like any now existing of the coast. The molluscan fauna of the locality is that of the usual Indian Oceanic type, with a slight admixture of Chinese and Philippine forms. In all recent beach remains in these parts of the world there is a large admixture of urchins, corals, &c. The aspect of the matrix was not of this character. It was much more like a blue-clay such as we have in Australia above the Mesozoic coal.

On the whole, I am inclined to regard the Labuan beds as of Oolitic age, and not Tertiary. Of the value of the coal-seams I had no means of judging. The amount on the surface showed that there was plenty to be had. Labuan is a naval coaling station. Stores of coal are brought out from England at a great expense for the use of her Majesty's navy, and if the same thing could be got in the island the enormous advantages are obvious. I think it should be further tested.

About fifty miles away to the south-east is the mouth of the Brunei river. Here the rocks are quite of a different character and much older. They are sandstones, shales, and grits, with ferruginous joints. The beds are inclined at angles of 25 to 45 degrees. They are often sieved into a kind of chert. At Moarra there is an outcrop of coal-seams 20, 25, and 26 feet thick. The coal is of excellent quality, quite bituminised and not brittle. The beds are

being worked by private enterprise. I saw no fossils, but the beds and the coal reminded me much of the older Australian coals along the Hunter River. The mines are of great value. They are rented for a few thousand dollars (by two enterprising Scotchmen) from the Sultan of Brunei. The same sovereign would part with the place altogether for little or nothing. Why not have our coaling station there? Or what if Germany, France, or Russia should purchase the same from the independent Sultan of Brunei?

The Sarawak coal beds I did not visit, but a collection of fossils was kindly sent to me by the Hon. Francis Maxwell, the Resident. I recognised at once well-known Australian and Indian forms, such as *Phyllotheca australis* and *Vertebraria*. These are entirely characteristic of the Newcastle deposits in New South Wales. The connection thus established between the Carboniferous deposits of India, Borneo, and [illegible] interesting.

I intend to publish in another form all the observations I have made on the coal formations of Borneo, which included fossils. The main result of all I have seen may be embodied in the following conclusions:—

(1) There are in Borneo immense coal deposits of different ages.

(2) These formations extend from the Palæozoic to Middle Mesozoic periods.

(3) The fossils from some of the beds are identical with those of certain well-known beds in India and Australia.

(4) The Labuan coals are probably in [illegible] not connected with any marine formation, [illegible] of Eolian origin.

J. B. Tennison

Labuan, Borneo, November 25, 1884.

THE PARIS CENTRAL SCHOOL OF ARTS AND MANUFACTURES

A RECENT article in *La Nature* describes the new buildings of the École Centrale des Arts et Manufactures. The school was founded in 1829 for 200 pupils by Dumas, Lavallée, Péclet, and Olivier. The buildings remained from that date until quite recently in the rue de Thorigny, but the want of space became more and more perceptible as the [illegible] spered, and in 1874 the Council proposed that the buildings should be abandoned, and they purchased a vacant plot of ground 6300 square metres in extent, site of the old St. Martin's Market, which abutted on streets. The principal advantage of this situation was that it faced the garden of the Conservatoire des Arts et Métiers, and was therefore within reach of the treasures of that establishment. The new buildings

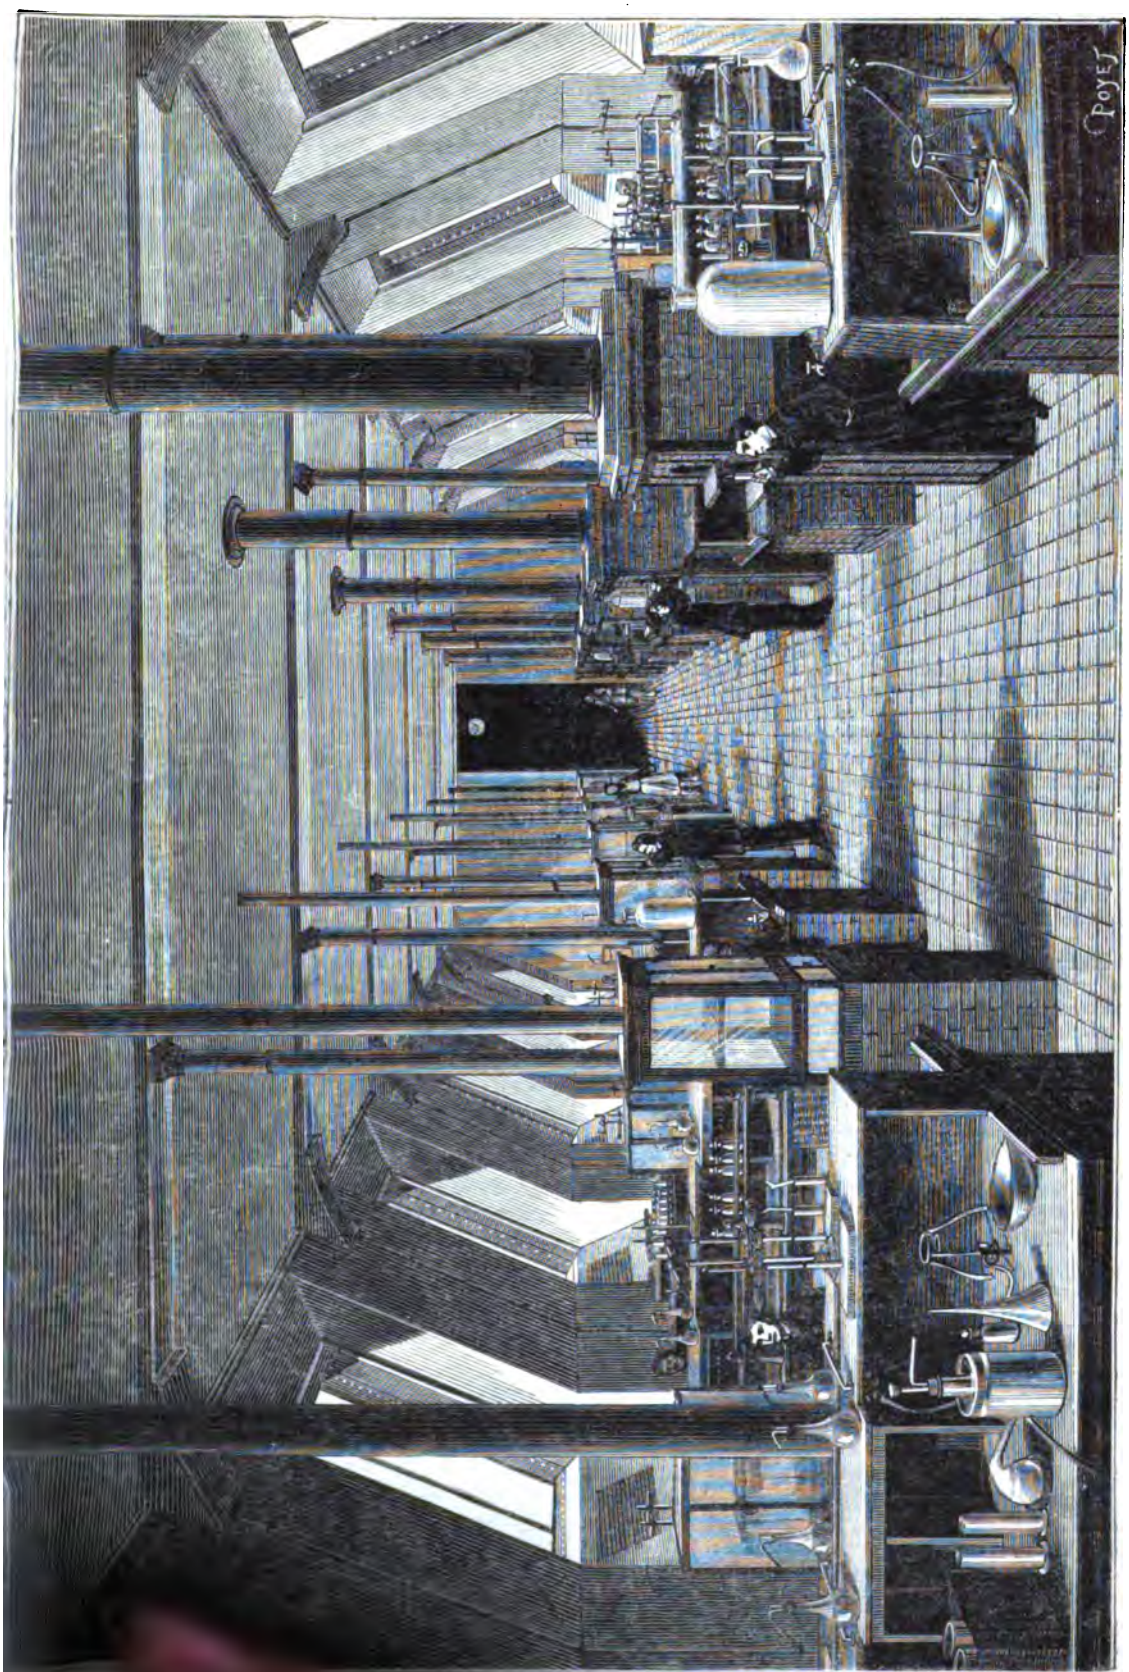

FIG. 2.—The New Central School: General View of the Great Laboratory or Third Year Students.

electricity employed for lighting purposes. The electrical works of the school are very remarkable. They include two engines, each of forty horse-power, which were presented by the makers. These work an Edison dynamo of 200 lamps, and three Gramme machines. The latter are each used alternately, and work six ventilators, which act over the whole building. Next to the electrical machines are two pumps which pump up water from a well; the school is also supplied with town water. Near the boilers is an Egrot alembic for distilling water for use in the laboratories. The steam from the water is conveyed by pipes into the laboratories, where it is employed in heating the water for washing, the stores, &c. In the basement are the cellars, store-rooms for glass, rooms for the study of stereotomy, for the construction of models, for stone-cutting, &c. The ground-floor includes a large court-yard, in the centre of which has been left the old fountain of St. Martin's Square. To the right of the entrance from the Rue Montgolfier is a staircase leading to a large vestibule, where the busts of the founders are placed. On this floor are the Mineralogical Museum, the dining-room of the Inspectors, stationery room, and the laboratory of industrial physics, the restaurants, the laboratory of industrial chemistry, and other special first year's laboratories, all opening on the court, the students working in the open air when dealing with noxious gases. The offices of the administrative body are on the first floor, and include director's and secretary's rooms, committee-rooms, steward's offices, and the like. These are lighted both by gas and electric light. The remaining rooms on the floor are devoted to students in their first year. Each storey has its large amphitheatre, capable of holding 250 students. These are formed at angles of the building, and are lit both by gas and electricity. The large blackboards behind the professors are raised and lowered by hydraulic machinery. The halls of study are ranged in two rows on one side of the building, with a corridor or passage between the rows for purpose of superintendence. Twelve pupils can occupy each room, and there are twenty-two rooms on each floor. The second and third stories are arranged on the same principle, except that on the former are the library and cabinets of collections. The fourth storey contains the large laboratories of the second and third year. The laboratory of the third year, of which an illustration is given, is the most important one in the school. Its appliances are of the most convenient and useful kind. Each student has all that he wants for his experiments at his hand.

NOTES

H.R.H. THE PRINCE OF WALES laid the first stone of the Museum of Science and Art and the National Library of Ireland on the 26th inst.

MR. RAPHAEL MELDOLA has been appointed Professor of Chemistry in the Finsbury Technical College in succession to DR. H. E. Armstrong, who holds the Professorship at the Central Institute.

A SPECIAL general meeting of the London section of the National Association of Science and Art Teachers will be held at the Technical College, Cowper Street, Finsbury, on Saturday next, the 25th inst., at 7.30 p.m., when Sir H. E. Roscoe, V.P.R.S., President of the Association, will deliver an address on its objects. All interested in the teaching of science and art are cordially invited to attend. The above association was started in Manchester about three years ago for the purpose of advancing the teaching of science and art and improving the position of teachers. It already has strong sections in Manchester, Liverpool, Birmingham, Newcastle, and other large towns in the north, and the London section was started last year.

MCGILL COLLEGE, Montreal, has received [illegible] last, two donations from the Hon. Donald A. Smith, [illegible] in the whole to 24,000*l.* sterling (120,000 dollars) [illegible] lishment of separate Lectures for Women, [illegible] ordinary B.A. or an equivalent degree.

THE project for making Paris a seaport was [illegible] the Congress of Learned Societies on the 5th inst. [illegible] by M. Bouquet de la Grye. He said the subject [illegible] ance from two points of view. The first and most [illegible] the military one. The defence of Paris demands [illegible] the establishment of a port which would secure [illegible] the capital and its suburbs at all times. The commercial [illegible] dustrial importance of the project is evident. The port [illegible] established in the Polasy basin, and the basin itself [illegible] to a mean depth of 6½ metres. M. de la Grye does [illegible] neither dams nor locks, but only the deepening of the [illegible] river by dredging. It could be executed in four [illegible] The total expense would be about 100 millions of francs.

DR. ROWELL, of Singapore, is stated to have made a [illegible] ichthyological addition to the Raffles Museum there, [illegible] of a very complete collection of the fish and [illegible] habiting the seas and rivers of the Malay Penin[illegible] Rowell, it is said, intends making a second [illegible] tion to send to the Italian and Colonial Exhibition [illegible] year.

THE *Bulletin* of the Essex Institute (U.S.) contains [illegible] on American archæology, by Mr. F. W. Putnam, [illegible] refers to chipped stone implements. Referring to [illegible] often made that the making of arrowheads [illegible] one of the lost arts, he says, that at the present time [illegible] Indians in America who continue to manufacture [illegible] even work pieces of glass bottles into symmetrical [illegible] arrowpoints. The method appears to be as follows: [illegible] of stone is selected and roughly shaped by striking [illegible] hammerstone. If it is found to chip readily, it is [illegible] further by light blows along the edges, each blow [illegible] chip. Partly wrapped in a piece of skin, it is [illegible] left hand and finished by flaking off little bits. The [illegible] part of the work is done with a flaking tool [illegible] piece of bone or antler. This is a few inches long [illegible] half an inch wide, having one end rubbed [illegible] edge, which may be either straight, pointed, or [illegible] other end is fastened to a piece of wood, or [illegible] support to the hand. Sometimes this wooden [illegible] enough to be held under the arm, thus steadying [illegible] which is grasped by the right hand. The edge of [illegible] pressed firmly against the edge of the stone that [illegible] rotation of the wrist a small flake is thrown [illegible] stone. With a little practice this flaking can be done [illegible] tolerable rapidity and precision. Some stones [illegible] being heated. The various forms of chipped [illegible] as scrapers, drills, knives, spearpoints, and [illegible] were made by the method here described.

ACCORDING to the *Colonies and India*, Baron [illegible] K.C.M.G., has issued, under the auspices of the [illegible] Government, a second supplement to the [illegible] Australian plants. It appears from the [illegible] lished that, whilst the known plants of Australia [illegible] are about 9000, they occur in the following [illegible] respective colonies—viz. Western Australia, [illegible] 3457; New South Wales, 3154; Northern [illegible] Victoria, 1820; South Australia, 1461, and [illegible] The progress of botanical discovery in Australia [illegible] quarter of a century has been very marked, and [illegible] mainly indebted to Baron Müller for the [illegible] ginning of the century (1803) Robert Brown, who [illegible]

ier of Australian botany, returned to England with 3000 and 4000 species of plants, and these in subsequent described in his "Prodromus Flora Novæ Hollandiæ a Van Diemen." From the days of Brown no syste- ork was added to his labours, until Baron Müller, con- that the time had arrived for the publication of a general f Australia, joined with the late Mr. Bentham in pre- and publishing the seven volumes of the "Flora ensis."

Lords of the Committee of the Council of Education ven their consent for a certain portion of the Buckland Collection to be exhibited in the aquarium during the ning International Inventions Exhibition. The selection, nde casts of various species of fish, models of vessels, es for catching fish, and apparatus for marine and fresh- h-culture. Such a combination of exhibits will prove a able source of attraction, and tend to popularise the a still further in the eyes of visitors to the Exhibition. etter purpose could the exceedingly interesting collection uckland Museum be utilised, hidden, as it has hitherto om general observation by its remote situation at South ton.

National Fish Culture Fishery at Delaford is now in working order, and a large number of fry have lately eed in the ponds, where they are thriving exceedingly well. he only *national* establishment in the United Kingdom ed for the purpose of acclimatising and culturing fish for fit of all communities, including all species of Salmonidæ se fish.

Zoological Society has been presented by the National ture Association with a young seal which has hitherto l one of the ponds in the Exhibition grounds, South ton. It was captured off the coast of Donegal, Ireland, a state of somnolence.

urrent number (No. 17) of *Die Natur* contains an article Emmerig, of Lauingen, on German bees as storm

From numerous observations, the writer advances ly the theory that on the approach of thunderstorms, nerwise gentle and harmless, become excited and exceed- table, and will at once attack any one, even their usual s, approaching their hives. A succession of instances n in which the barometer and hygrometer foretold a se bees remaining quiet, and no storm occurred; or the nts gave no intimation of a storm, but the bees for hours ere irritable, and the storm came. He concludes there- the conduct of bees is a reliable indication whether a impending over a certain district or not, and that, what- appearances, if bees are still, one need not fear a storm- pted to rain merely, the barometer and hygrometer are ables than bees; not so, however, in the case of a town. Finally, the writer trusts that his remarks on ot may lead to further observation.

ESSRS. SAMPSON LOW AND CO. announce that during the month they will publish "Under the Rays of the Aurora in the Land of the Lapps and Kvæns," an original y Dr. Sophus Tromholt, edited by Mr. Carl Siewers, narrative of journeys in Lapland, Finland, and Russia 882-83, and descriptions of the interesting Lapps and he book will contain an account of the labours of the ropolar scientific expeditions and a complete popular exposition of our present knowledge of the remarkable now known as the aurora borealis or northern lights, to of which the author has devoted the greater part of The work will also contain a map, chromo-lithographs, ous portraits, diagrams, &c., from photographs and drawings by the author, including numerous illustrations of the aurora borealis. Arrangements have been made for the publication of the work in France, Germany, Norway, Sweden, and Denmark.

MISS E. A. ORMEROD'S "Report of Observations of Injurious Insects and Common Farm Pests during the Year 1884, with Methods of Prevention and Remedy," has reached us. This issue is the eighth annual report that has been prepared by the author, and is much more bulky than any of its predecessors, extending to 122 pages. It embodies the remarks of numerous observers in various parts of the United Kingdom on the occurrence of insects injurious to farm and garden crops, the extent of their depredations, to which is often added suggestions for prevention and remedy. In glancing through the pages of this report it is not a little remarkable to notice how observant often of minute and interesting details Miss Ormerod's correspondents are, and, though many of them probably have little or no scientific training, their aptitude for observing the habits and effects of certain insects makes their records of considerable value. Setting aside the value accruing from the publication of the report under notice, Miss Ormerod has done a good work in inculcating such habits of observation amongst farmers and gardeners, who have opportunities such as few others have for noticing facts connected with the life-histories of such insects as destroy their crops. The plan of Miss Ormerod's report is alphabetical, arranged according to the name of the plant attacked—such, for instance, as the apple, beans, birds (with especial reference to the depredations of sparrows), cabbage, carrot, &c. Into the matter of the sparrows Miss Ormerod goes at considerable length. She says: "The subject of the great loss caused by sparrows still needs to be brought forward. The injury continues to be widespread and serious, not only with regard to corn, but likewise in fruit-farming districts, and to garden crops; and, to encourage those who are suffering under it to bestir themselves actively in getting rid of the pest, it is desirable to draw attention to some points connected with it which deserve consideration—such as what the *food* of the sparrow is during the whole year besides the corn which we see it robbing us of; what its habits are; and likewise whether, where sparrows have been destroyed during a series of years in any given area, that area has been infested *with more insects* or *with more of any special kind of insect*, than when the sparrows were there." Miss Ormerod's numerous correspondents all agree that sparrows will not feed on insects when seeds, grain, fruit, and other vegetable food is within reach, and that, consequently, their numbers must be kept down if any farm or garden crops are to be harvested. Miss Ormerod is careful to point out that in advocating a judicious destruction of the house-sparrow, other small birds are not included. With regard to the appearance of starlings in large numbers in insect-infested pea-fields, a correspondent at Kingsnorth, Kent, observed that the weevil began to commit serious damage, and although the peas grew away from this attack, Aphis followed, and "starlings by hundreds frequented the pea-fields, as also did numerous kinds of smaller insectivorous birds, *but not the sparrows, until the peas were large enough for them to pick it out of the pod.*" Amongst other subjects more fully treated of in the Report, are the hop aphis and common hop aphis, the willow beetle, and some special observations on the woolly fly, or ox bot fly. The report will prove of much value to farmers, gardeners, and those interested in vegetable growth, and is full of interesting facts of scientific value. It is published by Messrs. Simpkin, Marshall, and Co.

AT a meeting of the Asiatic Society of Japan held in Tokio on February 11, Mr. Eastlake read a paper on the Japanese poisonous snake, *Trigonocephalus blomhoffi*, called by the natives *Mamushi*. It ranges in length from a little over one foot to

nearly or quite two feet; the body is short and thick, the head triangular, half of it being covered by shields; the colour is earthy brown, with dark brown circular markings or spots; the belly is black, but the edges of the abdominal plates are whitish. The same snake has been observed in Japan, Formosa, Mongolia, Chihli, Sze-chuan, and Kiang-hsi. It is much dreaded by the Chinese, who give it several fanciful names; but its correct name is compounded of two ideographs meaning "worm" and "to strike," from the idea that it invariably inflicts two wounds. It derives one of its names ("only a day") from the notion that a person bitten by it lives only twenty-four hours. According to Kæmpfer, soldiers are fond of the flesh, and to this day it is highly esteemed as a febrifuge, and takes an important position in the Japanese pharmacopœia. The skin also is preserved as a talisman of singular efficacy. The popular belief is that the *mamushi* gives birth to its young through the mouth, but it is really oviparous. It is said by one native encyclopædia that if the flesh be thrown on the ground the earth in the vicinity begins to hiss and steam, that the fat eats holes into everything it touches, that it is covered with bristles like a pig, is seven or eight feet long, carries a sting in its tail, and finally, that it should be eaten with "plum vinegar," or the leaves of the water-pepper. Taken thus, it cures irregular circulation of the blood and stubborn ulcers. The bite is seldom fatal, but when it is so, death occurs from circulation in the pulmonary arteries, producing asphyxia. As is the case with all *Crotalidæ* bites—for the *mamushi* is allied to the American rattlesnake, though far less venomous—the young can inflict poisonous wounds immediately after birth. The poison canal runs directly through the fang, while with many other snakes it simply lies in the groove of the fang. This tooth, or fang, may be compared with the needle of a hypodermic syringe; under the microscope it is flat, elliptic, sharp-pointed, and curved inward. In treating the wound, external applications are useless. In eating, the *mamushi* does not make use of its poison fangs, refusing even to eat anything that is killed with its venom. It is a reptile of nocturnal habits.

The additions to the Zoological Society's Gardens during the past week include two Macaque Monkeys (*Macacus cynomolgus* ♂ ♀) from India, presented by Mr. A. J. McEwens, a Campbell's Monkey (*Cercopithecus campbelli* ♀) from West Africa, presented by Miss Lyster; a Wild Boar (*Sus scrofa* ♀), European, presented by the Rev. Horace Waller; an Emu (*Dromœus novæ hollandiæ*) from Australia, presented by Capt. J. E. Erskine, R.N.; two Gouldian Grass Finches (*Poephila gouldiæ*) from Australia, presented by Mr. Chas. N. Rosenfeld, two Turtle Doves (*Turtur communis*), British, presented by Miss Reinhold; a Common Badger (*Meles taxus*), British, a Toco Toucan (*Ramphastos toco*), two Guira Cuckoos (*Guira piririgua*), a Brazilian Caracara (*Polyborus brasiliensis*) from Brazil, a Short-tailed Albatross (*Diomedea brachyura*) from Antarctic Seas, four Pintails (*Dafila acuta* ♂ ♂ ♀ ♀), European, four Summer Ducks (*Ex sponsa* ♂ ♂ ♀ ♀) from North America, two Spotted-billed Ducks (*Anas poecilorhyncha* ♂ ♀) from India, deposited; two Summer Ducks (*Ex sponsa* ♂ ♀) from North America, four Mandarin Ducks (*Ex galericulata* ♂ ♂ ♀ ♀) from China, a Swinhoe's Pheasant (*Euplocamus swinhoii* ♂) from Formosa, a Common Spoonbill (*Platalea leucorodia*), European, purchased; three Black Swans (*Cygnus atratus*), bred in the Gardens.

OUR ASTRONOMICAL COLUMN

Halley's Comet in 1456.—"This comet cannot exhibit a greater degree of brightness than when it passes the perihelion in the month of June; it may then be observed some days before perihelion; it is visible at perihelion itself, and, when it has passed that point, it continues to approach the earth, and its brightness consequently increases for some [illegible] terms Pingré introduces his account of the [illegible] Halley's comet in 1456, when, from the vague [illegible] European chronicles which were available to him, [illegible] perihelion passage on June 8 at 22h. 10m. Paris [illegible] The comet was observed in China on the morning of [illegible] being put in possession of a much closer approximation [illegible] elements of the orbit of Halley's comet at this return [illegible] possible to deduce from the published records of Eastern [illegible] torians and the Chinese description of its track given by [illegible] Biot in the *Connaissance des Temps* for 1846. [illegible] few years since found in the National Library at Flo[illegible] manuscript of Paolo dal Pozzo Toscanelli, with a [illegible] which the positions of the comet and neighbouring [illegible] shown between June 8 and July 8, of which he [illegible] a *fac-simile* to Prof. Celoria of the Royal Observatory, Milan, who has utilised it for the determination of its [illegible] orbit. There are in all, positions on twenty-four [illegible] Celoria first compared the places of twenty-one stars [illegible] from the chart, with their places reduced from modern [illegible] to 1456·5, and found a mean correction of +2′ to [illegible] longitudes and +24′ to his latitudes—a rather [illegible] ment for that epoch. Whether Toscanelli obtained [illegible] from the catalogue of the Almagest, from that of Ulug [illegible] or some Arabian catalogue that had reached him, [illegible] appear. The corrections named were applied to [illegible] positions of the comet, and, assuming the [illegible] have been 17·9676 (this value corresponding to the [illegible] between 1378 and 1835), Celoria obtains a first set of [illegible] which are used in the formation of normal places and [illegible] equations, the solution of which leads him to the following probable elements of the comet's orbit, depending on [illegible] observations:—

Perihelion passage 1456, June 8·20875, Paris M.T.

Longitude of perihelion	... ...	298 56 47
,, ascending node	...	43 46 4
Inclination	...	17 37 27
Log. excentricity	...	9 99459
Log. perihelion distance	...	9 79363

Motion—retrograde.

On May 26·266 Paris M.T., about which time the [illegible] detected in China, the above elements give its position [illegible] 35° 43′, Decl. +23° 53′, distance from the earth [illegible] from the sun 0·646. On June 17·333, at R.A. 68° [illegible] + 40°·7, it was at its least distance from the earth [illegible] having then passed the perihelion about nine days, [illegible] less near the time that the comet created so much [illegible] brilliancy and magnitude. On July 8·339, when [illegible] observed by Toscanelli, its position was in R.A. [illegible] Decl. +7°·0′, distance from the earth, 1·051, and [illegible] 0·865.

The latest translation of the Chinese description [illegible] of the comet will be found in Williams's well-known [illegible] p. 77.

In addition to the observations of Halley's comet, [illegible] manuscripts supply observations of the comets of [illegible] 1457 (I. and II.), and 1472, and Prof. Celoria has [illegible] elements deduced therefrom of all, except that of [illegible] *Astronomische Nachrichten*. It appears beyond question, Prof. Celoria's own words, "Che le osservazioni [illegible] sono assai preziose, danno a Toscanelli il vanto di [illegible] d'ogni altro fatte intorno alle comete osservatori [illegible] dette, e rivelano in lui un osservatore abile [illegible] conoscenza sicura ed intera del cielo."

Irving represents Toscanelli as the correspondent [illegible] of Columbus. Montucla's account of him chiefly [illegible] erection of the gnomon in the Church of S. Maria [illegible] Florence, of which Ximenes published an [illegible] wherein Montucla thought he claimed for Toscanelli [illegible] was his due. As, however, Prof. Uzielli in [illegible] scrutches respecting him, we may soon be more fully [illegible] as to the works of one who certainly claims an honourable [illegible] in the history of observational astronomy.

The Total Solar Eclipse on September [illegible]—It will be remembered that during totality in the eclipse of December 1870, the planet Saturn was situate within the [illegible] but we are not sure that it was anywhere [illegible] At the time of totality in the eclipse [illegible]

nd the planet Jupiter will be similarly situated. Thus at iiddle of the eclipse at Castle Point, on the south-east coast : North Island, the distance of Jupiter from the moon's limb e 45′, and the angle of position from her centre about 26°. ere appears to be every probability that an expedition from ustralian observatories will take part in the observation of clipse on the shores of Cook's Straits, or in the vicinity of : Point.

GEOGRAPHICAL NOTES

rctic steamer *Alert*, which is about to be returned by rnment of the United States to that of Great Britain, lent by the latter to Canada for the continuance of the Bay Survey, for which purpose thirty thousand dollars ked from the Dominion Parliament.

last meeting of the Geographical Society of Munich s described his journey in South America, exploring -shed between the Paraguay and the Amazon. His is were the brothers Von den Steinen. Thay ascended uay by steamer, and after eighteen days' journey uyaba, the capital of the Brazilian province of Matto id the terminus of the steamship line on the river. got a military escort and provisions. After remain- weeks in Cuyaba they started, with three months' pro- l an escort of fifteen men, to cross the water shed to m. This elevation, which is only 300 to 400 metres presents the appearance of a savannah, broken up by follow the watercourses. The formation is sand- reddish clay, containing lumps of iron- plateau were very cold. The water- aries of the Amazon here were that the whole upper course source of the former under 11° south latitude. After the expedition had crossed the last tributary of the Tapajos, they reached, after eight days' journey, to the east, a large river. Here the oxen which remained healthy were killed, canoes were made from the bark of the Yatoba tree, and, after they had learnt that no larger river existed farther east, they began their voyage on the river, which, in honour of the governor of the province, was called Rio Batovy. The course is interrupted by numerous falls and rapids. In passing these obstacles the boats frequently capsized, and many valuable portions of the collections were lost. After a long and difficult voyage the party reached some Bacairi villages, the inhabitants of which were found wholly ignorant of metals. Through the Rio Batovy they reached a large river, undoubtedly the Xingu. Here they had a collision, which ended satisfactorily, with the Trumai Indians ; subsequently they came in friendly contact with the Suya, from whom they received much important information about the hydrography of the region. At 9° south latitude waterfalls were again reached, which rendered navigation difficult, although the river was here a kilometre in width. When their provisions were almost wholly exhausted they reached the settlements of the Yuruna Indians, who understood Portuguese, and received further supplies from them. From 8° to 3° S. the Xingu falls 200 metres in a series of cataracts. Under the guidance of the Yurunas these rapids were passed, and on October 15 the first Portuguese settlement was reached, and the travellers took steamer on the Amazon to Para, which they reached after five months spent in the most unknown regions of Brazil.

THE Vienna correspondent of the *Times* states that an extraordinary meeting of the Geographical Society of Vienna will shortly be held to welcome the Austrian African explorers, Dr. Paulitschke and Dr. von Hardegger. The Crown Prince of Austria will be present. The travellers started from Trieste on December 30, 1884, and chiefly explored the interior of the Gallas country. At Harrar, the largest town of East Africa, they were amicably received by the Egyptian governor, Abdallah, son of the Emir Mahomed Abdel Shakur, murdered in 1875. The Governor was just engaged in forming an army. On their return, on March 25, they found Zeila half in ruins. The Austrian explorers have established meteorological stations at Harrar and Zeila, which will be looked after by the English Consuls, Pitten and King. The collections they have brought with them, filling several cases, will constitute a very valuable addition to the Austrian Imperial Museum. The travellers will, in a few days, report personally to the Crown Prince, and submit a comprehensive statement of the commercial conditions of East Africa to the Minister of Commerce.

A PARLIAMENTARY paper (Corea, No. 2, 1885) issued during the past week contains a report by Mr. Carles, of the British Consulate at Seoul, of a journey made by him at the close of last year through Northern Corea. The journey lasted about six weeks, and appears to have extended over about 3000 *li*. Starting from Seoul, Mr. Carles went along the western coast road through Kaisong, Hwang-ju, Phyong Yang and An-ju to Wy-ju, where the river forming the boundary between China and Corea was reached. Having ascended the valley of this river several days' journey, he turned towards the east coast through Kang-ge and Ham-heung, to the treaty port of Gensan on the Sea of Japan, from whence it is about a week's journey back to the capital. Among the points noticeable in this excellent report, extending to thirty-two octavo pages, we observe that in Corea, as in a lesser degree in Japan, there is a great disproportion between the number of males and females, the former being more numerous. In the large towns this is ascribed to the immense staffs attached to the officials, but in the villages there is no corresponding balance in favour of females, and it is probable that an explanation which accounts for the disproportion by a greater number of deaths among girls in infancy is correct, for there was no evidence of female infanticide. Corea has been said to be a land of large hats, but this does not tell everything, One would hardly expect the following dimensions from this statement alone. At Phyong Yang, a large and historical town near the west coast, Mr. Carles records that the hats worn by the poor women are baskets 3½ feet long, 2½ feet wide, and 2½ feet deep, which conceal their faces as effectually as the white cloak worn by women of a better class over their heads. The men wear a basket of the same shape, but somewhat smaller. It, however, requires the use of both hands to keep it in place. A structure of a size but little larger, which is used to cover fishing-boats, suggests to the traveller that the women's hats

should be converted into coracles. Literature is honoured in Corea as in other Eastern countries, but the monument erected over the graves of the doctors of letters are at least unique. It consists of the trunk of a tree painted like a barber's pole, some 30 feet up. The top and branches are cut off, and on the summit rests a carved figure of slim proportions, 20 feet long, and with a forked tail in imitation of a Corean dragon. From the head, which resembles that of an alligator, depends cords on which brass bells and a wooden fish are strung. The total absence in even the most ancient and historical provincial towns of any remains of art and culture, leads Mr. Carles to think that perhaps the Coreans of olden days differed but little from that of the present time, and that her early civilisation has been greatly overrated. Frequent evidences of mineral wealth were observed. The contradictory reports on this subject are very perplexing. Not long since we published a statement from a traveller in Corea that there were few or no traces of mineral deposits, while the general impression has been that the country was very wealthy in gold, iron, and coal. Nothing but a special survey will set the question at rest. No map or sketch accompanies this report. Unfortunately maps of Corea are rare. An excellent one was published not long since in *Petermann's Mittheilungen*. It is compiled, with Mr. Satow's assistance, and under his supervision, from the maps of the Japanese general staff. A slight sketch-map of Corea would have rendered Mr. Carles's interesting report much more intelligible than it is at present.

THE last *Bulletin* of the American Geographical Society contains an account of the reception of Lieut. Greeley by the members of the Society, and a paper by Lieut. Schwatka describing his exploration on the Yukon River in 1883. A marvellous account is given of the ravages of the mosquito pest in Alaska during the warm months. Shooting on one occasion was out of the question, not altogether on account of the venomous attacks of these insects, but because they were so thick and dense that no one could have seen clearly through the mass in taking aim. Native dogs are killed by them under certain circumstances, and Lieut. Schwatka heard reports from persons so reliable that, coupled with his own experience, he never doubted them, that the great grizzly bear of these regions is at times compelled to succumb. "The statement seems preposterous, but the explanation is simple: the bear, in trespassing on a swampy habitation of mosquitoes, instead of seeking safety in flight, rears upon his hind-quarters and fights them bear-fashion until his eyes are closed by their repeated attacks on them, when starvation is the real cause of death."

THE German Foreign Office has made a communication to the Berlin Geographical Society on the changes in the political geography of South America (which were, the statement says, not inconsiderable) produced by the late war between Bolivia, Peru, and Chili. (1) By the treaty of Ancon of October 20, 1883, Peru ceded to Chili, "permanently and unconditionally," the coast-province of Tarapaca, the boundaries of which were declared to be "in the north the defile and River Camarones, in the south the defile and River Loa." This new Chilian province is, by a law of October 10, 1884, divided into two departments, Pisagua and Tarapaca. The latter, chief town Iquique, has for boundaries "towards the territory of Antofagasta the River Loa to Quillagua, and a line from the latter across the volcanoes Miño and Olca to the volcano Tua." The boundary between the two departments is formed by the Quebrada des Aruma to Curana, and from there to a point on the coast two kilometres from Caleta Buena. This change in the dominion of the respective States is regarded as final. But the two following appear to be regarded as provisional only. (2) Bolivia agreed, in the armistice convention concluded at Valparaiso on April 4, 1884, and ratified on November 20 last, that Chili shall hold provisionally (that is, during the armistice, the length of which is not defined) the coast of Bolivia from the 25th degree south latitude to the mouth of the Loa River, and eastward to the boundary line "from Sapalega to the volcano Licancaur, from there to the volcano Caveina, thence to the southern watercourse of Lake Ascotan, Mount Allaga, and the borders of Tarapaca." This portion of Bolivia corresponds to the Bolivian province of Atacama, and had not been organised by Chili at the commencement of the present year. (3) Peru, by Article 3 of the Treaty of Ancon, has ceded to Chili until March 28, 1894, the provinces of Tacna and Arica. This territory "is bounded on the north by the Sama River from its source in the chain of mountains on the frontiers of Bolivia, to the sea on the south by the defile and River Camarones." By the law of October 31, 1884, these form a single province of two departments (Tacna and Arica).

BEFORE the Royal Colonial Institute, on April 3, Sir [illegible] Justice Pinsent, of Newfoundland, read a most interesting paper on this oldest of British colonies. From a geographical point of view, the earlier and more antiquarian portion of the paper was the most interesting. The writer describes the visit of Sebastian Cabot and the early history of Newfoundland, which was originally given to the continent and then to Europe, and which, when divers parts were given different names, came to be applied only to that island which still bears the name which long lent to those discoveries their chief importance.

AT the meeting of the Paris Geographical Society on March 2, M. Venukoff communicated a letter which he had received from the Russian General Stebnitsky, reporting that Lieut. Guedenoff had completed a journey in the Trans-Caspian region with the object of determining the positions of various points in the basin of the Amu-Darya. He commenced at Kizil-Arvat, whence he went to Igdy, and thence towards Petro-Alexandrovsk by Khiva. He ascended the Oxus to Charjui, and from there through Southern Turkomania by Merv and Askabad. He travelled 1200 kilometres, and determined forty astronomical points. A letter was read which General Faidherbe had addressed to the Italian Geographical Society on the subject of doubts which had arisen in its *Bulletin* on the authenticity of the story of a journey of M. Bonnfanti to the Soudan and Timbuctoo. The latter traveller reports a conversation which he held on the subject with an "envoy" of Timbuctoo recently in Paris. The envoy declared he had seen this traveller in Timbuctoo, but repudiated the idea of his having been there.—M. de Rivoyre described the history of Obock, in the Red Sea, which now belongs to France. The position of this place and of Obock, he said, gave France a great advantage, which she could watch calmly the events now passing in Ethiopia.—M. Germain Bapst described his explorations in Armenia, on the frontiers of the three empires of Turkey, Russia, and Persia, and gave some interesting details of the semi-barbarous populations living in those regions.

THE last number (Bd. xix. Heft 6) of the *Zeitschrift der Gesellschaft für Erdkunde zu Berlin* contains a translation of Report on the Russian National Survey for 1887, and a tabulated catalogue of books, articles, maps, &c., published between November, 1883, and 1884, in the domain of geography.

THE SCOTTISH METEOROLOGICAL SOCIETY

AT the annual meeting on March 23, Dr. Archibald Buchan, F.R.S.E., in the chair, it was stated in the Report of Council that since last meeting in July two new observatories had been established—one at Leuchthie, Kirkcaldy, and the other at Comrie, Perthshire. During the summer the Assistant Secretary inspected twenty-six stations. In addition to the ordinary work of the office he had prepared a short account of the climate of the British Islands, embracing the results which would appear in next issue of the *Transactions*. At the Ben Nevis Observatory, the observations during the winter had been carried on by Mr. Omond and his assistants night and day, without the break of a night, even during a great storm which raged around the Observatory in February, when from 6 p.m. of the 22d to 7 a.m. of the following day such was the violence of the storm that for fourteen hours no light could be carried across the path, and thermometers could be read. The chairman moved a commission for the erection of a self-recorder for registering the movements at the Observatory, a grant of 200*l*. for the purpose having been obtained by Mr. George Dansers and Trustees from the Government Grant Committee. The total cost of erection and maintenance of the Observatory up to March 1884, was 5935*l*., which was 344 in excess of the subscriptions and other moneys received. The actual cost exceeded the originally estimated amount to upwards of 1000*l*. This excess arose chiefly from the additions it was found necessary to make to the buildings, the extra furnishings required in the kitchen, the great cost of making and maintaining the road, and the transport to the top of building materials and coals. It was hoped that the public, to whose [illegible] the observatory owed its existence, would by [illegible]

le the directors to place the Observatory in efficient working
r. The work at the Scottish Marine Station continues to
rosecuted with energy and success. The Council had re-
mended that the grant from the Fishery Fund of the Society
he year ending November next be increased from 250*l.* to
. In November, 1884, an application on the part of the
ed Salmon Commissioners was made to the Council for
ce and assistance in investigations which the Commissioners
resolved to undertake into the salmon disease, and questions
rally affecting the salmon fisheries; and the Commissioners
now carrying out a scheme of observations recommended
le Council.
r. John Murray read a report on the Scottish Marine Station,
ng that there is every reason to be satisfied with the support
h the Station is receiving and with the work done. A sum
456*l.* 13*s.* 1*d.* has up to the present time been received in
criptions from the general public, in which is to be added
lonation of 1000*l.* which led directly to the foundation of the
on. The Scottish Meteorological Society has promised an
al contribution of 300*l.* for three years, and for the present
the British Association has voted a grant of 100*l.* The
al Society of London and the Government Grant Committee
sanctioned grants to the amount of 520*l.* to assist scientific
who will carry on their researches chiefly by means of the
ances and conveniences offered by the Station. The total
nditure up to the present time for the equipment and main-
ce of the Station amounts to 2751*l.* 8*s.* 1*d.* The comple-
of the additions now in progress, and the maintenance of
tation till November 1, 1885, will cost a further sum of
At the request of a number of naturalists it is proposed
tablish a temporary laboratory at Millport, on the Clyde,
sufficient accommodation for its workers, during the months
ly and August of this year. The yacht *Medusa* will be in
dance to carry on dredging or assist in making observations
estuary of the Clyde or any of the lochs which open into
It is hoped that a permanent branch of the Station may
ately be established at Millport.
. H. R. Mill, B.Sc., submitted a detailed report of the
rological part of the work carried on at the Marine Station,
ich it was mentioned that plans of a new chemical laboratory
being prepared. A number of observations had been made
ertain the temperature and salinity of the water at the
e and the surface, and to find out the penetrability of light,
e found that a piece of photographic printing paper was
letely blackened by exposing it to 109 hours of daylight at
th of 30 feet, while at fifteen feet it was blackened by 42
exposure. As to the temperature, the general law seemed
that the range between summer and winter was nearly
ices as great at Aden and twice as great at Queensferry
ess at the Isle of May; and that in summer the temper-
of the water fell steadily from Aden to the May, and in
crease with equal uniformity. The variations in salinity
very slight from Inchkeith to the mouth of the Forth,
from Inchgarvie to Alloa they were very great both be-
high and low tide, bottom and surface, at the same place
tween differences on the Forth short distances apart.
ort on anemometrical observations at Dundee was read
. Cunningham, C.E., showing the diurnal velocity of
ind during the seasons and during cyclones and anti-
es. The daily maximum velocity occurred a little after
, and the minimum from midnight to 6 A.M. During
clones the velocity of the wind was less during the night
more than during winter, but stronger during the day.
Cunningham also showed an elaborate diagram he had
ed for facilitating hygrometric calculations. A paper by
mond was read, on the formation of snow-crystals from
Ben Nevis (NATURE, vol. xxxi. p. 533), and a paper by
achan, on the meteorology of Ben Nevis to February,

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

IDGE.—The Report of the Examiners in the last
idge Local Examinations speaks very favourably of the
and Algebra papers. Trigonometry and Mechanics were
adly at some centres, but very well at others; the seniors
ll in Statics, but the majority of candidates answered
in Astronomy.
Spherical Chemistry a larger proportion of juniors than last year gained high marks, and the percentage of failures was considerably less than in the theoretical paper. A few seniors sent in very good answers, but the greater number wrote answers to which it was difficult to attach a definite meaning. The phenomena and principles of Chemistry were evidently quite unreal to most of the senior candidates.

In Heat the juniors did rather worse than last year; book-work was fairly done, but the simpler laws and principles were often converted into utter nonsense. The seniors as a whole answered badly; many were quite unfamiliar with most elementary facts and every-day occurrences, and had no notion of scientific methods or accurate reasoning.

In Statics, Hydrostatics, &c., the work was moderately well done; but the questions on Dynamics and Friction were very unsatisfactorily answered by the seniors.

Electricity and Magnetism showed a slight improvement.

Biology showed a large percentage of failures, owing to inadequate practical study.

Botany was ill done by most juniors; inaccurate descriptions and incorrect use of terminology were prominent. Many seniors showed fair knowledge of at least some part of the subject. Morphology and Classification of Flowering Plants, with descriptions of specimens, were the weakest parts of the examination.

In Zoology many of the junior candidates were quite unfit to enter for the examination; antiquated text-books and inefficient teaching were answerable for this. The seniors did slightly better, but had little practical knowledge of animals.

In Physical Geography all but a few did inferior papers, having learnt some facts and reasons by rote, without attempting to understand them. There was, in most cases, complete ignorance of the meaning of sections and contour lines.

UNIVERSITY OF NEW ZEALAND.—The annual meeting of the Senate of this University was recently held at Auckland, and extended over several days at the end of February and beginning of March. In consequence of the death of the Chancellor, Mr. Henry John Tancred, who had held office for twelve years, the Vice-Chancellor, Dr. James Hector, F.R.S., C.M.G., &c., was elected to the Chancellorship, and Rev. J. C. Andrew was chosen Vice-Chancellor. Dr. Hector, as Chancellor-Elect, announced, on the authority of Sir Julius Vogel, that the Government contemplated the establishment of four scholarships for the promotion of scientific and technical education, the management and administration of which were to be intrusted to the University. They would be tenable for eight years, and would be open to pupils from any school in the colony, or to competitors at any industrial exhibition, subject to an examination equal to the fourth standard of primary schools. Holders of these scholarships would spend the first four years at a secondary school, the next three in a University course, in preparation for a science degree, and the last year in preparation for taking honours in science.

The report of the Vice-Chancellor dealt mainly with local matters, but referred to the attendance of an ex-Vice-Chancellor as a representative of the University at the tercentenary celebration of the University of Edinburgh, and to the election by the Senate of new examiners during the previous year. It may not be generally known to English readers that all the degree examinations of this University are conducted entirely by papers set and printed in England, and that the answers are revised by the English examiners, who in all cases either are, or have been, examiners for the Universities of London, Cambridge, or Oxford. The standard maintained is, as nearly as possible, that of the University of London. More than eighty candidates presented themselves at the degree examinations last November from a population not exceeding half a million. The agent for the University in England is Mr. Wm. Last Carpenter, B.A., B.Sc., of Harlesden, London, N.W.

SCIENTIFIC SERIALS

Journal of the Franklin Institute, No. 711, March, 1885.—E. A. Glaeser, on tidal theory and tidal predictions.—Prof. E. J. Houston, glimpses of the International Electrical Exhibition, No. VI. Melsonaugh's telephonic inventions. This gives an interesting account of the instruments invented by McDonough between the years 1867 and 1870, the receiver of which anticipated in all its main features the form of receiver introduced by Graham Bell.—Prof. C. A. Young, physical constitution of the sun, a lecture delivered at the Electrical Exhibition, illustrated

with many cuts.—C. E. Fritts, on the Fritts selenium cells and batteries. These cells, in which the light enters through a film of gold-leaf appear to have a much lower resistance than any other selenium cell.—Prof. E. J. Houston, on Delaney's facsimile telegraphic transmission. This number of the journal is also accompanied by reports of the Examiners of certain Sections of the late Philadelphia Exhibition, including electric telegraphs, dental appliances, and applications of electricity to warfare.

Bulletin de l'Académie Royale de Belgique, February 7.—Experimental and analytical researches on the action and conclusion of gases at various temperatures, by M. Hirn.—A study of the physical aspect of the planet Jupiter, by F. Terby.—Researches on the spectrum of carbon in the electric arc in connection with the spectra of the comets and the sun, by Ch. Fievez.—Remarks on the application of electricity to aerial navigation, by MM. Gérard, Van Weddingen and Jacques.—On the agreement between atmospheric variations and the indications of colours in stellar scintillations, by Ch. Montigny.—On the presence of chiastolite rocks in the Lower Devonian formation of the Belgian Ardennes, by E. Dupont.—A new formula applicable to the development of functions, and especially of integers, by Ch. Lagrange.—Remarks on Massy's Glossary of the Egyptian novel of Setna, by M. Wagener.—The death of Don Juan of Austria, by Baron Kervyn de Letienhove.

Engler's Botanische Jahrbücher, Sechster Band (1885), Heft 1.—Emilius Koehne, Lythraceæ, der Bau der Blüthen. Though the majority of the plants of this order are clearly entomophilous, the author is compelled to regard certain species as cleistogamic, *e.g.* species of *Ammannia* and *Rotala*.—A. Engler, Beiträge zur Flora des südlichen Japan und der Liu-kiu-Inseln.—J. C. Maximowicz, *Amaryllidaceæ sinico-japonicæ*.—A. G. Nathorst, Notizen über die Phanerogamenflora Grönlands im Norden von Melville Bay.—Litteraturbericht.

Heft 2.—T. F. Cheeseman, Die naturalisirten Pflanzen des Provincial-Districts Auckland. The author is inclined to conclude that the struggle between the naturalised and the indigenous flora will result in a limitation of the distribution of the indigenous species, rather than in their actual extinction. It must be confessed, however, that some few indigenous species appear to have already become extinct.—A. Peter, Ueber spontane und künstliche Gartenbastarde der Gattung *Hieracium*, sect. *Pilosellaeformia*.—F. Hildebrand, Ueber *Hederanthera usteriifolia*. The plant develops differently according as it grows in shallower or in deeper water; in the latter case float-leaves are formed, which differ widely in form from the ordinary leaves of the plant (one plate).—Lad. Celakovsky, Linné's Antheil an der Lehre von der Metamorphose der Pflanze. The author concludes, from careful study of the writings of Linnæus and his pupils, that Linnæus definitely laid down the fundamental principle of metamorphosis before Wolff and Goethe.—Litteraturbericht.

Heft 3.—Franz Buchenau, Die Juncaceen aus Indien (plates 2 and 3).—E. Hackel, Die auf der Expedition S.M.S. *Gazelle* von Dr. Naumann gesammelten Gramineen.—H. Dingler, Der Aufbau des Weinstockes (plate 4).—A. Engler, Beiträge zur Kenntniss der Araceæ, vi.—A. Engler, Eine neue Schinopsis.—Beiblatt, short notice of Apospory, and of Treub's discoveries on the sexual reproduction of *Lycopodium*.—Litteraturbericht.

Journal de Physique, March.—Prof. Mascart, on the employment of the method, of damping for determining the value of the ohm.—L. Bleekrode, experimental researches on the refraction of liquefied gases. These are determined by the method of De Chaulnes.—L. Cailletet, new apparatus for preparing solid carbonic acid.—M. Vaschy, note on the theory of telephonic apparatus.—G. Meslin, on the definition of perfect gases, and on the resulting properties. The author objects to the usual statement of the combined laws, because it rests upon the definition of temperature, which again rests upon the properties of perfect gases. He proposes to deduce all gaseous laws from the following definitions:—"A perfect gas is one which perfectly obeys the law of Mariotte at all temperatures, and for which there is no change in the (true) specific heat when the volume changes."—R. T. Glazebrook, on a method of measuring the electrical capacity of a condenser (abstract from *Phil. Mag.*).—C. R. Alder-Wright and C. Thompson, on the variation of chemical affinity in terms of electromotive force (from *Phil. Mag.*).—W. Hankel, on the electricity developed during certain processes evolving gases.—F. Kramer, Descartes and the law of refraction of light. A polemic to show that the accusation made against Descartes of having appropriated the discovery is [illegible] founded.—A. Genocchi, on some writings concerning [illegible] tions of the pendulum and the experiment of Foucault.

Rivista Scientifico-Industriale, March 15.—[illegible] made by Prof. Tito Martini with an accumulator of [illegible] type modified by Antonio Trevisan.—Influence of the [illegible] of the condensor on electric sparks, and their [illegible] nection with the hypothesis which considers electricity [illegible] incompressible fluid, by Dr. Pietro Cardani.—Results [illegible] Trouvé universal incandescent electric lamps (numerous illustrations), by the Editor.—Experimental researches [illegible] action of boric acid in the human system in [illegible] epidemics and contagious diseases, by Prof. Philippo [illegible] —On a method for extracting chlorophyll, by E. Luggi[illegible] —On certain so-called "thunderbolts" of volcanic origin found on Mount St. Angelo, near Barzano, and in [illegible] places east of Lake Bracciano, by Prof. G. Snaver[illegible]

SOCIETIES AND ACADEMIES

LONDON

Royal Society, April 16.—"On the Agency of Volcanic Eruptions, with some Observations on the [illegible] of the Earth's Crust from a Geological Point of View [illegible] the Primary Cause of Volcanic Action." By Joseph [illegible] F.R.S., Professor of Geology in the University of Oxford.

That water plays an important part in volcanic [illegible] well-established fact, but there is a difference of opinion [illegible] whether it should be regarded as a primary or a [illegible] agent, and as to the time, place, and mode of its [illegible] The author gives the opinions of Daubeny, Poulett Scrope, Mallet, and, dismissing the first and last as not meeting [illegible] of geologists proceeds to examine the grounds of Scrope's [illegible] thesis—the one generally accepted in this country—[illegible] that the rise of lava in a volcanic vent is occasioned [illegible] pansion of volumes of high pressure steam generated [illegible] interior of a mass of liquefied and heated mineral matter [illegible] or beneath the eruptive orifice, or that volcanic [illegible] be attributed to the escape of high pressure steam existing [illegible] interior of the earth. The way in which the water [illegible] and where is not explained, but as the expulsion of it is considered to be due to the force of the [illegible] of course, necessary that it should extend to the very [illegible] volcanic foci, just as it is necessary that the powder [illegible] the breech of the gun to effect the expulsion of the ball.

The author then proceeds to state his objections to [illegible] thesis. In the first place he questions whether it is [illegible] water to penetrate to a heated or molten magma [illegible] solid crust. The stratigraphical difficulties are not [illegible] able, although it is well known that the quantity of [illegible] the depths actually reached in mines decreases, as a [illegible] the depth, and is less in the Palæozoic than in the [illegible] Kainozoic strata.

The main difficulty is thermo-dynamical. As the vapour of water increases with the rise of temperature faster at high than at low temperatures, the pressure [illegible] a depth of about 7500 feet and with a temperature [illegible] thermometric gradient at 48 feet per 1° F. [illegible] equal to that of one atmosphere only—would [illegible] 15,000 feet and a temperature of 302°, be equal to [illegible] spheres, and at 20,000 feet and temperature of [illegible] exceed 25 atmospheres. Beyond this temperature [illegible] has only been determined by empirical formulæ, which [illegible] increase of pressure is nearly proportional to the [illegible] the excess of temperature, would show that the [illegible] presence of the heat at greater depths, becomes [illegible] if the formulæ hold good to the critical point of water [illegible] there would at that temperature be a pressure of [illegible] atmospheres.

At temperatures exceeding 1093° F. and depth of [illegible] feet, the experiments of M. H. Ste. Claire Deville [illegible] that the vapour of water, under certain conditions, [illegible] undergoes disassociation, and, consequently, a large [illegible] volume. It would follow also on this that if [illegible] had been subject to the long-continued action of [illegible] peratures of great depths, we might expect to [illegible] amount of steam and a larger proportion of its constituents than occurs in the eruptions. Capillarity [illegible] and pressure will cause the [illegible]

alile depths, but with the increasing heat capillarity lowes ower.

king these various conditions into consideration, the author ds whether the surface-waters can penetrate to depths of than seven to eight miles, and feels it impossible to accept ypothesis based upon an assumed percolation to unlimited hs. That there should be open fissures through which r could penetrate to the volcanic foci, he also considers an ssibility.

t the objection to which the author attaches most weight ot the extravasation of the lava being due to the presence of ur in the volcanic foci, is, that if such were the case, there ld be a distinct relation between the discharge of the lava of the vapour, whereas the result of an examination of a ber of well-recorded eruptions shows that the two operations n no relation and are perfectly independent. Sometimes has been a large discharge of lava and little or no escape eam, and at other times there have been paroxysmal explo- eruptions with little discharge of lava.

ere are instances in which the lava of Vesuvius has welled almost with the tranquility of a water-spring. A great ion of Etna commenced with violent explosions and ejec- of scoriæ, which, after sixteen days, ceased, but the flow of continued for four months without further explosions. In ruption of Santorin, 1866, the rock-emission proceeded for in silence, the protruded mass of lava forming a hill nearly eet long by 200 feet high, which a witness compared with teady and uninterrupted growth of a soap-bubble. The ions of Mauna Loa are remarkable for their magnitude, t the same time for their quiet. Speaking of the eruptions 55, Dana says there was no earthquake, no internal thun- gs, and no premonitions. A vent or fissure was formed, which a vast body of liquid lava flowed rapidly but y, and without steam explosions, for the space of many hs.

the other hand, paroxysmal eruptions are generally ac- anied by earthquakes, and begin with one powerful burst, ed rapidly by a succession of explosions, and commonly little extrusion of lava, although it is to be observed that a quantity must be blown into scoriæ and lost in the ejec- Such was the eruption of Coseguina in 1835, and of ltea in 1883. Sometimes in these paroxysmal eruptions is absolutely no escape of lava, scoriæ alone being pro- A common feature in eruptions, and which indicates rmination of the crisis, is the stopping of the lava, though aseous explosions continue for some time with scarcely ished energy.

ere is thus no definite relation between the quantity of ex- e gases and vapours and the quantity of lava. If the on of lava depended on the occluded vapour, it is not easy how there could be great flows without a large escape of , or large volumes of vapour without lava. The extrusion a has been compared to the boiling over of a viscid sub- in a vessel, but the cases are not analogous.

only logical way in which it would seem possible for to be present is on the hypothesis of Sterry Hunt who es the molten magma to be a re-melted mass of the earlier ntary strata, which had been originally subject to surface eteoric action. But in the end the preceding objections equally to this view.

re is the further general objection to the presence of water molten magma, in that were the extrusion of lava due to ause, the extrusion of granite and other molten rocks do not, as a rule, lie so deep as the lava magma) should een the first to feel its influence and to show its presence. hough water is present, it is in such small quantities that ocks never exhibit the scoriaceous character which lava so nly possesses.

is lava always scoriaceous, as it should be if the hypo- were correct. Many lavas are perfectly compact and free apour-cavities, and so also are especially most of the great of lava (basalt) which welled out through fissures in late cal times. These vast fissure eruptions, which in India erica cover thousands of square miles, and are several nd feet thick, seem conclusive against water agency, for ve welled out evidently in a state of great fluidity, with ely little explosive accompaniments, and often without a f scoriæ mounds. The general presence of non-hydrated nd minerals is also incompatible with the permeation of hich the assumption involves.

It has been suggested by some writers that large subterranean cavities may exist at depths in which the vapour of water is stored under high pressure, but the author shows that such natural cavities are highly improbable in any rocks, and impossible in calcareous strata.

The author proceeds to account for the presence of the enormous quantity of the vapour of water, so constantly present in eruptions, and which, in one eruption of Etna, was estimated by Fouqué to be equal to about 5,000,000 gallons in the twenty-four hours. He refers it to the surface-waters gaining access *during the eruptions* to the volcanic ducts either in the volcanic mountain itself, or at comparatively moderate depths beneath. He describes how the springs and wells are influenced by volcanic outbursts. By some observers, these effects have been referred to the influence of dry and wet seasons, but there are so many recorded instances by competent witnesses, as to leave little doubt of the fact. This was also the decision of the inquiry by the late Prof. Phillips, who asks, Why is the drying up of the wells and springs an indication of coming disaster?

The author then considers the hydro-geological condition of the underground waters. He points to the well-known fact, that on the surface of volcanoes the whole of the rainfall disappears at once, and shows that when the mountain is at rest, the underground water must behave as in ordinary sedimentary strata. Therefore, the water will remain stored in the body of the mountain, in the interstices of the rocks and scoriæ, and in the many empty lava-tunnels and cavities. The level of this water will rise with the height of the mountain, and he estimates that it has at times reached in Etna a height of 5000 to 6000 feet, while the permanent level of the springs at the base of the mountain seems to be at about 2000 feet. The water does not, however, form one common reservoir, but is divided into a number of independent levels by the irregular distribution of the scoriæ, lava, &c. These beds are traversed by vertical dykes running radially from the crater, so that, as they generally admit of the passage of water, the dykes serve as conduits to carry the water to the central duct.

Little is known of the sedimentary strata on which volcanoes stand. In Naples, however, an artesian well found them under the volcanic materials in usual succession, and with several water-bearing beds, from one of which, at a depth of 1524 feet, a spring of water rose to the surface with a discharge of 440 gallons per minute. When in a state of rest the surplus underground waters escape in the ordinary way by springs on the surface, or when the strata crop out in the sea, they then form submarine springs.

During an eruption these conditions are completely changed. The ascending lava, as it crashes through the solid plug formed during a lengthened period of repose, comes in contact with the water lodged around or, may be, in the duct, which is at once flashed into steam, and gives rise to explosions more or less violent. These explosions rend the mountain, and fresh fissures are formed which further serve to carry the water to the duct from which they proceed; or they may serve as channels for the sea-water to flood the crater, when, as in the case of Coseguina and Krakatoa, the volcano is near the sea-level. As the eruption continues, the water-stores immediately around the duct become exhausted, and then the water lodged in the more distant parts of the mountain rushes in to supply the void, and the explosions are violent and prolonged according to the available volume of water in the volcanic beds. When this store is exhausted, the same process will go on with the underlying water-bearing sedimentary strata traversed by the volcanic duct.

The author gives diagrams showing the position of the water-levels *before*, *during*, and *after* eruption; and describes in manner in which, if the strata surrounding the duct and below the sea-level become exhausted, the efflux of the fresh water which passed out to sea through the permeable beds, when the inland waters stood at their normal height above the sea level, these same beds will in their turn serve as channels for the sea-water to restore the lowered water-level inland. Thus, the ex-current channels which carried the land waters into the sea-bed, and there formed, as they often do off the coasts of the Mediterranean, powerful fresh-water springs, now serve as channels for an in-current stream of sea-water, which, like the fresh water it replaces, passes into the volcanic duct. This agrees with the fact that fresh-water remains are common in many eruptions, and marine diatomaceous remains in others; also that the products of decomposition of sea-water are so abundant during and at the close of eruptions. With the fall of the water-levels, the

available supply of water becomes exhausted, or the channels of communication impeded, and this continues until, with the ceasing of the extravasation of the lava, the eruption comes to an end.

The author then explains the way in which the water may gain access to the lava in the duct, notwithstanding heat and pressure. This he considers to be dependent upon the difference between the statical and the kinetical pressure of the column of lava on the sides of the duct. In the change from the one state to the other, when the lava begins to flow, and its lateral pressure is lessened, the equilibrium with the surrounding elastic high pressure vapour becomes destroyed, and the vapour forces its way into the ascending lava. As this proceeds, the heated water further from the duct, and held back by the pressure of the vapour, flashes into steam to supply its place. If that water should be lodged in the joints of the surrounding rock, blocks of it will also be blown off, driven into, and ejected with, the ascending lava, as have been the blocks in Somma and of other volcanoes.

It is the double action thus established between the inland- and sea-waters that has probably prolonged the activity of the existing volcanoes settled in ocean centres, or along coast-lines, while the great inland volcanic areas of Auvergne, the Eifel, Central Asia, &c., have become dormant or extinct.

But if water only plays a secondary part in volcanic eruptions, to what is the motive power which causes the extravasation of the lava to be attributed? This involves questions connected with the solidity of the globe far more hypothetical and difficult of proof. The author first takes into consideration the probable thickness of the earth's crust from a geological point of view, and shows, that although the present stability of the earth's surface renders it evident that the hypothesis of a thin crust resting on a fluid nucleus is untenable, it is equally difficult to reconcile certain geological phenomena with a globe solid throughout, or even with a very thick crust. The geological phenomena on which he relies in proof of a crust of small thickness, are:—(1) Its flexibility as exhibited down to the most recent mountain uplifts, and in the elevation of continental areas. (2) The increase of temperature with depth. (3) The volcanic phenomena of the present day, and the outwelling of the vast sheets of trappean rocks during late geological periods.

He considers that the squeezing and doubling up of the strata in mountain-chains—as, for example, the 200 miles of originally horizontal strata in the Alps, crushed into a space of 130 miles (and in some cases the compression is still greater)—can only be accounted for on the assumption of a thin crust resting on a yielding substratum, for the strata have been as only a free surface-plate could to the deformation caused by lateral pressure. If the globe were solid, or the crust of great thickness, there would have been *crushing* and *fracture*, but not *corrugations*. Looking at the dimensions of these folds, it is evident also that the plate could not be of any great thickness. This in connection with the increase of heat with depth, and the rise of the molten lava through volcanic ducts, which, if too long, would allow the lava to consolidate, leads the author to believe that the outer solid crust may be less even than twenty miles thick.

That the crust does possess great mobility is shown by the fact that since the Glacial period there have been movements of continental upheaval—to at least the extent of 1500 to 1800 feet—that within more recent times they have extended to the height of 300 to 400 feet or more, and they have not yet entirely ceased.

With regard to the suggestion of the late Prof. Hopkins that the lava lies in molten lakes at various depths beneath the surface, the author finds it difficult to conceive their isolation as separate and independent local igneous centres, in presence of the large areas occupied by modern and by recently extinct volcanoes. But the chief objection is, that if such lakes existed they would tend to depletion, and as they could not be replenished from surrounding areas, the surface above would cave in and become depressed, whereas areas of volcanic activity are usually areas of elevation, and the great basaltic outwellings of Colorado and Utah, instead of being accompanied by depression, form tracts raised 5000 to 12,000 feet above the sea-level.

These slow secular upheavals and depressions, this domed elevation of great volcanic areas, the author thinks most compatible with the movement of a thin crust on a slowly yielding viscid body or layer, also of no great thickness, and wrapping round a solid nucleus. The viscid magma is thus compressed between the two solids, and while yielding in places to compression, it, as a consequence of its [illegible] like proportion in contemporaneous areas. In such instances the imposing slow movements of elevation which so long been going on along almost all the [illegible] shores of the Polar Seas, and to the area of [illegible] so often further south subtend the upheaved district.

With respect to the primary causes of these changes and extravasation of lavas, the author sees no hypothesis [illegible] all the conditions of the case so well as the old [illegible] secular refrigeration and contraction of a heated [illegible] solid crust—not as originally held, with a fluid nucleus, the modifications which he has named, and with a [illegible] compatible with the conclusions of the eminent physicists who have investigated this part of the problem. Although the loss of terrestrial heat by radiation is now exceedingly small, and the contraction needed for the quantity of lava ejected [illegible] long since calculated that, supposing five volcanic eruptions take place annually, it would require a century to reduce the radius of the earth to the extent of 1 mm., or about [illegible]

The author therefore concludes that, while the [illegible] of the lava is due to the latter causes, the process [illegible] due alone to the surface and underground waters which comes into contact as it rises through the volcanic [illegible] violence of the eruption being in exact proportion to the [illegible] which so gains access.

Geologists' Association, April 9.—A short paper [illegible] Notes on the Oldhaven pebble-beds at Caterham [illegible] Mr. T. V. Holmes, F.G.S.. The workmen at the [illegible] adjoining the Caterham Waterworks recently exposed a cavity in the pebble-beds, which was visible when [illegible] and Mr. R. Meldola visited the spot in December [illegible] cylindrical in shape, from ten to eleven feet in [illegible] five to six in diameter, its axis being nearly vertical. [illegible] of the existence of others was noted, and it was [illegible] similar hollows are by no means rare in these [illegible] cavities doubtless owed their origin to the existence [illegible] the chalk beneath, which pipes, from the superior [illegible] and there, of the upper strata of gravel as compared [illegible] lower, had not been entirely filled up. Examples [illegible] hollows elsewhere were given. The existence of [illegible] modified "loam with flints" in the midst of the [illegible] also noted, and the writer explained how they [illegible] accounted for without recourse to the hypothesis of [illegible] —On the Glacial Drifts of Norfolk, by Mr. H. [illegible] F.G.S. After describing the general character of [illegible] Norfolk, Mr. Woodward alluded to the difficulties [illegible] the subdivisions in different areas, for the beds are [illegible] no infallible guides are furnished by lithological [illegible] fossils, or even by stratigraphical sequence. Looking [illegible] broad way, two divisions might be made out: (1) the [illegible] Glacial, including the Cromer Till, Contorted Drift [illegible] called Middle Glacial; and (2) the Upper Glacial [illegible] chalky boulder clay and cannon-shot gravel. These [illegible] are borne out in part by the evidence of superposition [illegible] the character of the stones imbedded in the boulder [illegible] in part by the evidence that the contortions in the [illegible] Glacial beds were produced by the agent which [illegible] chalky boulder clay. Mr. Woodward expressed his opinion [illegible] the shells found in the Middle Glacial sands did not [illegible] the Glacial period, but were derived in part from Pliocene [illegible] north of Norfolk, now either entirely removed or [illegible] beneath the waters of the North Sea. The shells, which [illegible] forms that lived during the period of the coralline [illegible] were supposed by some authorities to have migrated [illegible] Mediterranean area during submergence of the [illegible] times and at an interval when the climate was [illegible] was drawn to the occurrence of boulder-clay in the [illegible] Glacial deposits near Hertford; and it was pointed [illegible] shells derived from the coralline and Red crags had been [illegible] by Mr. T. F. Jamieson in the drift of Aberdeenshire [illegible] that Pliocene deposits had formerly extended as far [illegible] Scotland. Briefly alluding to the method of [illegible] glacial drifts, Mr. Woodward passed on to notice the [illegible] of Palæolithic implements. The mammalian remains [illegible] with these belonged to the group which characterised the [illegible] Thames Valley deposits and were met with [illegible] Bank. When these deposits were accumulated, [illegible] Ouse joined the waters of the Thames and [illegible] now covered by the North Sea.

nthropological Institute, April 14.—Prof. Flower, .S., Vice-President, in the chair.—The election of J. G. ter, H. R. H. Gosselin, and J. Browne was announced.—Dr. . Garson read a paper on the inhabitants of Tierra del go. Three tribes inhabit the archipelago of Tierra del go: they are called the Onas, who inhabit the north and shores, and resemble the Patagonians in being a tall race, fly living by hunting, but supplementing their food with l-fish and other marine animals; the Yahgans, who live on shores of the Beagle Channel and southern islands, and are a t stunted race, subsisting almost entirely on the products of sea and birds; the Alaculoofs, who dwell on the western ds and are very similar to the Yaghans. These last two s and their characters were chiefly discussed, being better wn to us. They lead a very degraded life, wandering about place to place, possess no houses, but construct shelters out e branches of trees and build canoes of bark; they wear little clothing of any kind. In stature they are short, the averaging about 5 feet 3 inches and the women about et. In the character of their skull and skeleton they nble the other wild native tribes of America, but by isolation assumed certain characters peculiar to themselves. The lation of the Fuegian Islands appears to be about 3000. h information is still required regarding the people and their l customs. The osteological characters of the Yahgans pointed out and discussed.

Edinburgh

athematical Society, April 10.—Mr. A. J. G. Barclay, dent, in the chair.—Mr. T. B. Sprague, F.R.S.E., con-ted a paper, which was read by Prof. Chrystal, on the erminate form 0°; and Mr. John Alison discussed the rties of the so-called Simson line.

oyal Physical Society, April 15, Prof. John Duns, D.D., S.E., President, in the chair.—The President read a paper bnormalities of Development and the Reproduction of Lost in Living Organisms, with exhibition of *Tiliqua fernandi*, other specimens.—Mr. H. M. Cadell, B.Sc., H.M. Geo-l Survey, communicated notes on contorted shales below ill in Craigleith Quarry. These were very fine examples, e observed them below the boulder clay on the east side of uarry in 1880. The non-bituminous shales overlying the tone were at some places turned up, and curled over as if me heavy body, which might either have been the great heet which moved from west to east across the country g the glacial period, or icebergs sailing along at a later part e same period, and striking the bottom with projecting rs. The fact that the shales were twisted in different ions seemed to favour the iceberg theory in this instance. adell also referred to contortions of the edges of the same of shales in the Suburban Railway cutting at Meggetland ear Craiglockhart Hill. Bending over of the edges of &c., was sometimes seen in cases where the strata dipped h angles into the face of a slope, and this might lead an rienced geologist into great perplexity. This kind of g was due simply to gravitation, and had nothing to do e action. Mr. F. E. Beddard, M.A., F.R.S.E., F.Z.S., unicated a note on the anatomy of a new species of earth-belonging to the genus *Acanthodrilus*.—Mr. W. Ivison lam, F.C.S., referred to the presence of *Fragillaria* in ed quantities in the water supply of Elie, in Fife. The was stated to be a somewhat rare one, and was found in er beds in such quantities as to form a complete coat, and e frequent renewal of the beds.

Paris

demy of Sciences, April 13.—M. Boulay, President, in air.—Theorems relating to the actinometric functions of le plaques, by M. Haton de la Goupillière.—Remarks on eleton of a cave hyæna (*Hyæna spelæa*) discovered by ix Regnault, and presented to the Academy by M. Albert y. These remains, recently found in the Gargas district, Pyrenees, confirm the view already advanced by the that the cave hyæna was merely a heavy variety of the *crocuta* (spotted hyæna), still surviving in Central Africa. the pathogenetic and prophylactic action of the comma s, by M. J. Ferran. From experiments made on several subjects, whose names are given, the author concludes that by hypodermic injections of this germ, man, as well as the guinea-pig, may be infected with true cholera morbus, and that immunity from further attacks may be obtained by such injections in more or less graduated doses. He proposes to repeat the experiments here described in the presence of a Commission appointed by the Academy.—On the so-called "herpolhodie," a transformation on the fixed cone of the "polhodie," already described, by M. A. Mannheim.—Further results in the theory of matrices: their distribution into species, and formation of all the species, by M. Ed. Weyr.—A new method of determining the constants α, γ, δ, of the large mirror M of the sextant, by M. Gruey.—On the law of densities in the interior of the earth, in connection with M. Tisserand's theory of the figure of the earth, by M. R. Radau.—Resistance experienced by an indefinite circular cylinder immersed in a fluid to move as a pendulum in a direction perpendicular to its axis, by M. J. Boussinesq.—On the phenomena of diffraction produced by an opaque screen of rectilinear outlines, by M. Gouy. Two points are considered: the diffraction of light within the shadow of the screen when the ambient medium is more refringent than the atmosphere, and diffraction without the shadow of the screen.—On the phenomena presented by the permanent gases when evaporated in vacuum; on the limits within which the hydrogen thermometer may be employed, and on the temperature obtained by the explosion of liquefied hydrogen, by M. S. Wroblewski.—Influence of dilution on the coefficient of lowering of the freezing-point for substances dissolved in water, by M. F. M. Raoult.—On the vibratory forms of square plaques, by M. C. Decharme.—Description of some important improvements recently effected in the gas-heated thermo-electric pile invented in 1874 by MM. Clamond and J. Charpentier.—On a new electric pile acting with two fluids, by M. A. Dupré.—On the diurnal variation of the magnetic elements at the Parc Saint-Maur Observatory during the years 1883 and 1884, by M. Th. Morceaux.—On the depths to which the solar rays penetrate in marine water, by MM. H. Fol and Ed. Sarasin. From a series of experiments made in the month of March, 1885, at Villefranche-sur-Mer (Mediterranean) analogous to those previously carried out at the Lake of Geneva, the authors conclude that in fine weather the last rays of light are dissipated in the Mediterranean at a depth of about 400 m. below the surface.—On a remarkable deviation of the trajectory of a cyclone observed last February on the north-east coast of Madagascar, by M. Pelagaud. Almost for the first time since the Indian Ocean has been visited by Europeans—that is, the last four hundred years—a cyclone has visited the Island of Madagascar, causing great damage to the French fleet and other shipping along the north-east coast.—Note on the oxides of copper, by M. Joannis.—On the mutual attraction of bodies in solution and solid bodies immersed in the fluid, by M. J. Thoulet. In this second note the author shows that such mutual attraction exists that it is instantaneous, and that in the normal conditions it is directly proportioned to the surface of the immersed solid.—On a new process for preparing cyanogen, by M. G. Jacquemin.—Quantitative analysis of cyanogen mixed with carbonic acid, nitrogen, oxygen, and other gases, by the same author.—On the primary haloid derivatives of ordinary ether, by M. L. Henry.—On the existence of a nervous system in the Peltogaster: a contribution to the history of the Kentrogonides (Rhizocephals of Fritz Müller), by M. J. Delage.—On the nervous system of the Bothryocephalids, by M. J. Niemiec.—Notes on three new species of Ascidians from the coast of Provence, by M. L. Roule.—A new contribution to the question of boric acid of non-volcanic origin, by M. Dieulafait. It is shown that boric acid is not always of volcanic origin, but that vast quantities exist in the salt lakes and saline marshes, all the elements of which are of a sedimentary character, and which amid more or less complex physical and chemical changes have still their first origin in the evaporation of normal marine basins.—On some specimens from a remarkable fossil forest in the Reserve of the Navajos Indians, Arizona, by M. E. Desté.—Note on the springs in the district of Gabes, North Africa, by M. L. Dru.—On the work being accomplished at the station of Kondoâ, established by the French section of the African International Society, by M. Bloyet.—On the influence of the nervous system on the temperature of the body, by M. Ch. Richet.—Studies on the inhalation of formene, and of monochlorinetted [illegible] of methyl), by MM. J. Regnault and Villejean[illegible] less character of the comma bacillus, and on

germs in the atmosphere, by M. J. Héricourt. The author finds that these organisms are normally present in all kinds of water, and in the form of spores or germs everywhere in the atmosphere. There are many varieties, some apparently identical with the comma bacillus of cholera.

BERLIN

Physical Society, March 6.—Dr. Kalischer described a new secondary battery intended to overcome the disadvantage of the usual accumulators, namely, that the sheet of lead used as anode got very soon destroyed. This object he attained by adopting a very concentrated solution of nitrate of lead as electrolyte, and iron as anode. The iron, on being immersed in the solution of lead, became passive and resisted every corroding effect of the fluid; in other respects the peroxide of lead on the electric charge became deposited at the anode as a very firm coherent mass enveloping and protecting the iron on all sides. The charge was continued till the greater part of the nitrate of lead was decomposed, a condition which was marked by the occurrence of a greater development of gas at the anode. At the beginning of the charge all development of gas must be avoided, as otherwise the peroxide of lead, or, more correctly, the hydrate of peroxide of lead, became covered with bubbles. As kathode a sheet of lead was used, but it was attended by two disadvantages. In the first place the lead, during the charge, separated itself at the kathode into long crystal threads, which soon passed through the fluid and produced short closing (of the current). In the second place the nitric acid, which remained in the fluid after the separation of the lead, acted very powerfully on the sheet of lead. Both disadvantages Dr. Kalischer avoided by amalgamating the kathode. This accumulator of iron, concentrated solution of nitrate of lead, and amalgamised lead yielded, after the electric charge, which could be carried out without any special precautions, a current of about 2 volts; after about six hours' discharge, however, the electromotive force sank to 1·7 volts, but, on the battery being left to itself for twenty-four hours, it became a little increased. According to the measurements hitherto taken, the functions of this accumulator were satisfactory. An attempt to substitute sulphuric manganese for nitric lead in this battery did not answer the purpose, as the peroxide of manganese separated itself, not in a continuous layer, but in loose scales.—Prof. Schwalbe laid before the Society a piece of a piezometer which had burst under a pressure of ten atmospheres. The rather thick glass was traversed by longitudinal fissures, distributed with perfect regularity and exactly parallel to each other.—Prof. Schwalbe further spoke of the ice-outcroppings, resembling asbestos and glossy-like silk, which emerged on old, decayed twigs and branches, and which he had observed in former winters. He supposed that they originated in the crystallisation outwards of needles of ice from the water in the interior of the wood under moderate and slowly advancing colds. This winter also, as in former winters, he had succeeded in effecting these glacial outgrowths artificially on some twigs, by impregnating them with water and then exposing them to a slow increasing cold of from −2° to −3°. To test the accuracy of this hypothesis, he instituted experiments with solutions of salt. A solution of nitre gave very satisfactory results. When a decayed twig was thoroughly saturated with a solution of nitre, and then left to evaporate, there then cropped out on it delicate glossy protuberances, perfectly similar to those observed in nature on moist pieces of wood. In this last case it was impossible that any increment could come from the outside; these crystal needles could have grown only from the interior. With the cube-crystallising kitchen salt, on the other hand, the experiment did not succeed. The speaker related that the first observations of these ice outcroppages were made by the Duke of Argyll. The pillar-like outgrowths which in recent times had been largely observed by English naturalists, and which he had formerly observed and described, were, in the opinion of the speaker, likewise excrescences from the interior.—Dr. Kayser read a paper, sent in by Dr. Müller-Erzbach, in which the latter endeavoured to refute some objections raised against his experiments, communicated to the Society at the last sitting, respecting the magnitude of the sphere of influence of molecular attraction.

March 20.—Dr. Gross, starting from theoretical considerations, instituted the following experiment:—Two iron electrodes overlaid with sealing wax, in such a manner as to leave only the terminal planes free, were dipped into solution of chloride of iron, closed by means of a [illegible] into a circle, and any inequalities there might happen to be adjusted according to the Poggendorff-Du Bois method. When now one electrode was surrounded by a magnetising spiral, there was seen, on its being [illegible] electric current passing from the magnetic electrode through the fluid to the non-magnetic electrode. It might [illegible] that the current was a thermo-electric one, produced by warming of the magnetising spiral; but a delicate [illegible] showed that the air within the magnetising spiral was not warmer than the surrounding air. Besides, the electrode which was to be magnetised was surrounded by a [illegible] through which water of a temperature 12° below the [illegible] was constantly flowing; and yet, notwithstanding the powerfully cooling influence, the current always passed from the magnetic to the non-magnetic electrode, whereas a thermo-current must have passed from the warm to the cold electrode. The electric current was, therefore, produced, not by a difference of temperature, but by the magnetisation of the one electrode. The current continued so long as the electrode was magnetised. If the electrodes were now brought into a tube, and so arranged to lie behind each other in the axis of the tube, with their terminal planes turned to each other, then, on the magnetisation of one electrode, an electric current again set in, passing, however, from the non-magnetic electrode, through the fluid to the magnetic electrode. The direction of the current was consequently dependent on the direction of the magnetism in the electrolyte and the second electrode. As conducting fluids sulphates of iron could be used in these experiments, but these only such as received the free terminal planes of the electrodes nakedly. Dr. Gross believed that the [illegible] illustrated by him in the experiments thus described was [illegible] the thermo-electric currents between magnetic and [illegible] netic iron wires, which were a subject of study to [illegible] Thomson.

LONDON

THURSDAY, APRIL 23

OCIETY, at 4.30.—Magnetisation of Iron: Dr. Hopkinson, F.R.S.—on Changes produced by Magnetisation in the Length of Rods of Iron, and Nickel: Shelford Bidwell.—The Essential Nature of the ng of Phytophagous Larvæ (and their Pupæ); with an Account of Experiments upon the Relation between the Colour of such Larvæ d of their Food-Plants: E. P. Poulton.

OF ARTS, at 8.—The Chemistry of Essilage: F. J. Lloyd.

OF TELEGRAPH ENGINEERS, at 8.

STITUTION, at 3.—Natural Forces and Energies: Prof. Tyndall.

TION OF CIVIL ENGINEERS, at 8.—On the Seat of Electromotive n a Voltaic Cell: Prof. Oliver Lodge.—Electrical Definitions, diance, and Notation: Andrew Jamieson, F.R.S.E.

FRIDAY, APRIL 24.

MICROSCOPICAL CLUB, at 8.—On a New Flagellate: Dr. Barth. Economy of the Hive Bee: F. Cheshire.

STITUTION, at 9.—British Fossil Cycads: W. Carruthers.

SATURDAY, APRIL 25.

SOCIETY, at 3.—On the Theory of Illumination in a Fog; and anchromatic Telescope with Applications to Photometry: Lord h, F.R.S.—On Compound Dynamo Machines: Prof. A. W. F.R.S.—On the Determination of the Heat Capacity of a ester: J. W. Clarke.

TY ASSOCIATION, at 2.—Visit to the Zoological Gardens: Dromedaries, by Dr. P. L. Sclater, at the Kangaroo Sheds, on Marsupial Edentata, and their Relation to Extinct Forms.

STITUTION, at 3.—Fir-trees and their Allies: W. Carruthers.

OLD CLUB, at 6.30.

MONDAY, APRIL 27.

OGRAPHICAL SOCIETY, at 8.30.—Letter announcing the Ascent of Ruwenzori, British Guiana: Everard im Thurn.—Notes on the ro Ronoma and Ascent of the Mountain: H. J. Perkins.

TUESDAY, APRIL 28.

STITUTION, at 3.—Digestion and Nutrition: Prof. Gamgee.

CIETY, at 8.—The Practical Importance of Gaseous Ophthalmoscopy.

LOGICAL INSTITUTE, at 8.—On the Past and Present Condition n Rude Stone Monuments in Westmorland: A. L. Lewis.—ural Constructions near Carnac: Rear-Admiral F. S. Trenchard.—ng-Sacrifices or Ancient Sacrificial Stone of the North-West Canada: M. Jean L'Heureux, Government Interpreter to the Indians.

WEDNESDAY, APRIL 29.

L SOCIETY, at 8.—On the Structure of the Ambulacra of some ers and Species of Regular Echinoidea: Prof. P. Martin F.R.S.—The Physical Condition Involved in the Injection Ex-nd Cooling of Igneous Masses: H. J. Johnston-Lavis, M.D.—al Period in Australia: R. von Lendenfeld, Ph.D. Communicated Plantford, F.R.S.

THURSDAY, APRIL 30.

STITUTION, at 3.—National Forces and Energies: Prof. Tyndall.

N OF MECHANICAL ENGINEERS, at 7.30.—Description of the utomatic Machine Gun: Hiram S. Maxim.—Abstract of Reuleaux's ements on Riveted Joints, with their Applications to Practical ents: Alexander B. W. Kennedy (including the latest experiments of Alexander B. W. Kennedy's Report issued to the Members in February). in Prof. Kennedy's Report issued to the Members in February).—ries of the Trilinear Spherical Eccentric: M. Louis Peaucellier.—n of a Blooming Mill with Balanced Top Roll at the Ebbw Vale alvert D. Holland.

FRIDAY, MAY 1.

STITUTION, at 1.30.—Annual Meeting

STITUTION, at 9.—Water Jets and Water Drops: Lord Rayleigh.

SATURDAY, MAY 2.

STITUTION, at 3.—Fir-trees and their Allies: W. Carruthers.

RD WARD has pleasure in announcing the issue of a new Micro-Slide of Zoophyte, with tentacles in special manner so well known to his numerous patrons.

EDWARD STANFORD'S NEW PUBLICATIONS.

Now Ready, Cheap Edition, Fcap. 8vo. Cloth, with 8 Maps and 23 Illustrations, 2s.

EPPING FOREST. By EDWARD NORTH BUXTON, Verderer.

"Mr. Buxton goes about his work in a thoroughly practical way. His book is plentifully furnished with accurate maps, and about thirty pages are occupied with simple and clear directions as to the several walks which may be taken through the Forest. It may be safely said that any one who carefully follows Mr. Buxton's directions will obtain a perfectly new conception of the Forest and its peculiar beauties. The book is illustrated by some charming drawings of forest scenes, and by numerous delicately executed woodcuts of birds and flowers."—*Times*.

"Mr. Buxton has rendered a great service to the public in general, and to Londoners in particular, in preparing a book which must henceforth take the first place among the Guides to Epping Forest."—*Saturday Review*.

Just Published, Small Post 8vo, with Plan, Cloth, 3s.

VISITOR'S GUIDE to SIENA and SAN GIMIGNANO. By J. L. BEVIR, M.A., Author of "Visitor's Guide to Orvieto."

Third Edition, Revised, 18mo. Cloth, 2s. 6d.

CELESTIAL MOTIONS; a Handy Book of Astronomy. With Two Plates. By W. T. LYNN, B.A., F.R.A.S., formerly of the Royal Observatory, Greenwich.

"Can be most sincerely and heartily recommended."—*Science Gossip*.

NEW MAPS.

THE RUSSO-AFGHAN FRONTIER.—STANFORD'S SHILLING MAP of AFGHANISTAN and ADJOINING COUNTRIES, on the scale of 76 miles to an inch. Revised to March 23, 1885. One Sheet, Coloured, size 18 by 20 inches. Price: Folded Sheet, 1s.; post free, 1s. 1d. Unfolded, packed on roller, post free, 1s. 6d.; mounted, in cloth case, 3s.; post free, 3s. 2d.

MAP of the ACQUISITIONS of RUSSIA IN EUROPE and WESTERN ASIA, corrected up to a recent date, giving Distances Advanced, Dates, and Population. New Edition. Coloured Sheet, price 3s. post free, 3s. 3d. on roller, 5s. 6d.; mounted in case, 5s., post free, 5s. 3d.

London: EDWARD STANFORD, 55, Charing Cross, S.W.

MAGIC SQUARES; New Methods, embracing a General Method. 30 Illustrations. Price 1s. 6d. R. S. Harvey, Printer, Pleasance Street, Dundee.

S. N. STOUT.

In Casks, 12/6 per 9 gals. In Bottle, 3/3 per doz. Impl. Pts.*

* Bottles charged 2/- per doz., and allowed at the same rate if returned; but they must be paid for with the Beer.

Neither sugar, saccharine, nor any of the many new Brewing Materials are used in the manufacture of the "S. N." Stout; it is Brewed entirely from the finest Malt and Hops; it is, too, more hopped than Stout is generally; therefore, besides being very nutritious, it is an excellent Tonic and particularly suited for invalids, ladies nursing, or anyone requiring a good strengthening beverage. It is a "Sound Nutritious" Tonic, and very much recommended by Medical men.

CHORLTON & DUGDALE, MANCHESTER.

The REMINGTON "PERFECTED" TYPE-WRITER

A MACHINE to supersede the pen for manuscript writing, correspondence, &c., having twice the speed of the pen; is always ready for use; simple in construction, not liable to get out of order, easily understood. It is used in Government Offices, and by Merchants, Bankers, Lawyers, Clergymen, Doctors, Scientists, &c.

"The other advantages of the machine, those for which chiefly I personally value and employ it, are worthy of a moment's consideration. Its work in my hands is about twice as rapid as that of a pen, and became so after a few weeks of practice. I have worked the machine for eight consecutive hours without more than ten minutes' interruption, and at the end of that time my hands were not conscious of the least fatigue. Every writer is aware that the same thing cannot be said with regard to the pen.—ROBERT HOUDEWELL CANTRE, F.R.C.S., &c."

No. 2 PERFECTED TYPE-WRITER. CAPITALS AND SMALL LETTERS.

"The Times, Tuesday, ... "The chief use of the ... said to be for ... rapid and legible ... tion of short-hand notes, ... tion of manuscript for the ... vised. ...

"In the preparation of ... vision or for the press, ... type-writer sees the ... There is, first, the greater ... rion; and next, the ... duct. The work of the ... comparable in a greater ... looked and revised with the ... necessary alterations ... tion with a pen. ... by the type-writer ought ... almost precisely the ... finally appear."

London: KEGAN PAUL, TRENCH & CO.

Just Published, with Illustrations, 8vo, Cloth, 2s.

On CERTAIN INDICATIONS of the

EXISTENCE of an ALLOTROPIC MODIFICATION of ELEMENTARY NITROGEN, and on the SYNTHESIS of AMMONIA.

By GEORGE STILLINGFLEET JOHNSON.

J. and A. CHURCHILL, 11, New Burlington Street.

SCOTTISH PROVIDENT INSTITUTION.

EDINBURGH—6, ST. ANDREW SQUARE. LONDON OFFICE—17, KING WILLIAM STREET, E.C.

At the 47th ANNUAL MEETING on 25th March, 1885, the Directors reported a satisfactory result of the Year's business. The Proposals received, £1,170,615 10s., being somewhat above, while the amount accepted is somewhat under, the last Year.

New Assurances completed, **£1,015,155; with Premiums, £35,274.**

Income in Year, £688,920. Claims, £269,880.

Realised Funds (increased in year by £327,540) **exceed £5,000,000.**

Only two Offices in the Kingdom (both much older) have as large a Fund.

WHOLE WORLD LICENCES AND NON-FORFEITURE OF POLICIES.

Policies are generally now free from restrictions on residence **after five years,** and **unchallengeable** on any ground but fraud. Policies may be revived on payment of premium within the year without proof of health. In case of death, when the unpaid premium exceeds the unpaid premium, the full sum is payable, under deduction of Arrears.

The Advantages which this Institution offers to Assurers are—

A Larger Original Assurance—say £1200 or £1250 for the Premium charged elsewhere (with Profits) for £1000.

The Prudent, to Good Lives, of Large Additions—no share being given to those by whose early death there is a loss.

Claims under Policies now payable a Month after Proof.

Reports, with Tables of Premiums, &c., on Application.

J. MUIR LEITCH, London Secretary.

JAMES WATSON, Manager.

Next week. Medium 8vo, Price 21s.

A TEXT-BOOK of PHARMACOLOGY, THERAPEUTICS, and MATERIA MEDICA.

By T. LAUDER BRUNTON, M.D., D.Sc., F.R.S.,

Fellow of the Royal College of Physicians; Assistant Physician and Lecturer on Materia Medica at St. Bartholomew's Hospital; Examiner in Materia Medica in the University of London, in the Victoria University, and in the Royal College of Physicians, London; late Examiner in the University of Edinburgh.

ADAPTED TO THE UNITED STATES PHARMACOPŒIA BY FRANCIS H. WILLIAMS, M.D. BOSTON, MASS.

BY THE SAME AUTHOR.

In the Press,

DISORDERS OF DIGESTION: THEIR CONSEQUENCES AND TREATMENT.

This work contains, in addition to the Lettsomian Lectures, a number of other Papers by the Author on similar subjects.

FOSSIL MAMMALIA IN THE BRITISH MUSEUM

gue of the Fossil Mammalia in the British seum (*Natural History*). Part I., containing the ers Primates, Chiroptera, Insectivora, Carnivora, Rodentia. By Richard Lydekker, B.A., F.G.S., (London: Printed by order of the Trustees, 1885).

he above-named volume we welcome another con-bution to the series of descriptive catalogues of atural History Section of the British Museum, initiated by the late indefatigable Keeper of the ical Department, Dr. J. E. Gray, have been ener-ly extended under the direction of his eminent sor, Dr. Günther, himself the author of the greatest n all, the now classical "Catalogue of Fishes." ke that valuable work, however, and the subse-published catalogues of Chiroptera, of birds, and rachia, the volume before us does not conceal, the modest title of "Catalogue," a systematic on the orders dealt with, for it includes even less s title implies, dealing only, as a rule, with the ens of fossil Mammalia exhibited in the Museum s. We regret that this is so; an excellent oppor-has been lost by the author of bringing out a aph, complete to date, of all the species of fossil ls known—a work urgently needed not only by ent of palæontology, but by biologists in general, successful study of existing animals depends so on their knowledge of extinct forms.

ugh the subjects of this work belong as truly to logical series as any of the groups of animals of in the catalogues of the Zoological Depart-ove referred to, yet, as their remains which form erial on which it is founded are conventionally "fossils," the volume is prefaced by the learned the Department of Geology, Dr. Henry Wood-This is, no doubt, as it ought to be, for Dr. Wood-not only a distinguished palæontologist but a also; but the circumstance points to the un-able fact that the collections on which it is based a part of the house different from that of their elations—a condition which, however convenient rtmental reasons, is none the less to be deplored ary to the principles which should govern the ent of a collection intended for instruction, and g to the general non-scientific visitor, who is ly led by such an arrangement to regard the whose remains are presented thus to his view, res of a parentage altogether distinct from that g species. We are confident that our opinions subject are shared by the able director of the whose arrangement of the specimens in the n Collection of the Royal College of Surgeons d on the natural, as opposed to the artificial, sys-as we see adopted at South Kensington, which, existed there before his appointment, and which, is still forced upon him by circumstances not control.

eeper of the Department of Geology is fortunate in having obtained for the preparation of this catalogue the services of one so competent to deal with the subject as Mr. Lydekker, whose valuable palæontological papers, published chiefly in the Memoirs of the Geological Survey of India, are so well known, and who appears to have brought to the study of the collection a mind unbiassed by theories of a bygone period of natural history, save in a few points which we shall presently point out, in which we trust he may have yielded rather to the respect due to the opinions of a former master of this science than to his own convictions.

The author premises (in the Introduction) that he has endeavoured, as far as possible, to follow in the lines laid down by Prof. W. H. Flower (in his "Catalogue of Specimens of Vertebrated Animals in the Museum of the Royal College of Surgeons," Part II., 1884) in respect to the nomenclature of species and genera and in regard to general systematic arrangement, and his wisdom in following such an excellent model is much to be commended. Unfortunately, however, the proviso "as far as possible" seems to have opened the way to some considerable exceptions to this good rule, which prove to be serious blemishes in a work otherwise well carried out. We can see no good reason why the simple plan of printing references in the body of the page, employed in all hitherto published descriptive catalogues of the Natural History Department, should have been abandoned in the volume before us in favour of a complicated system of foot-notes which disfigure the pages and causes the unlucky reader to keep his eyes perpetually on the move. Thus (to cite one of many instances), under the genus *Machærodus* we find arranged, in a narrow line down one side of the page, six synonyms, each provided with a minute number referring to a certain similarly numbered foot-note at the bottom of the page, in which, when found, the required reference may be made out. This trouble could have been spared the reader by simply printing the reference after the synonyms, and much space would also have been saved. But worse than this is the absence of even footnote references to synonyms, such as we notice in many places, as, for instance, under "*Hyæna striata*," where eleven synonyms with the names of their authors only, are arranged in a dismal line down the left side of the page.

Although the fossil remains are, in most cases, very carefully described, yet we regret to find but few definitions in detail of the families, genera, or species; for although definitions of still existing genera and species might possibly be omitted or much abridged, it is surely unadvisable in a descriptive catalogue to omit or abridge those of any of the truly fossil forms, however well they may be known to professed palæontologists. The author is occasionally unfortunate even in his short definitions, as, for instance, where he defines the genus *Crossopus* as having "teeth nearly the same in number as in *Sorex*, but different in colour," whereas this genus is really distinguished by having teeth nearly the same in colour as *Sorex*, but different in number (one premolar less on each side above). The expression "nearly the same in number" is curious in a scientific work. Under this genus we notice that *C. remifer*, which we considered had been long ago recognised as a synonym of *C. fodiens*, is given position as a distinct species, and, wonderful to

relate, it owes its recognition as such to two rami of the mandible!

We were at first puzzled by the numbers applied to certain premolars in the author's description of the dentition of some fossil species belonging to still existing genera, until the following paragraph in the Introduction was noticed:—"In enumerating the teeth of the typical heterodont Eutherian mammals, each tooth of the cheek-series is referred to its proper position in the complete series, the first premolar always meaning the first tooth in the typical series of four, and so with the succeeding teeth." Mr. Lydekker has therefore resuscitated what we had thought was long defunct—namely, the Owenian system of expressing the homology of the teeth by imagining a fixed mode of reduction for a typical number of 44, of which the premolars, for instance, when reduced in number, are supposed to become so by symmetrical loss from before backwards; so that when, for example, two upper premolars alone remain, these must be considered to be the third and fourth. It is, however, an incontrovertible fact that in many species of mammals it is the third premolar in the upper jaw that is wanting, that further reduction is accomplished by the loss of the second, and, lastly, of the first premolar, the fourth premolar of the original series alone remaining, this tooth very rarely disappearing also. In the lower jaw of certain species with three premolars the second premolar is the first to disappear, so that here the same difficulty exists. Were the mandible of such a species to become fossil, the two remaining premolars would, by the Owenian system, be recognised as the third and fourth, whereas they would really be either the second and fourth or the first and fourth. Indeed Prof. Owen himself notices ("Anat. Vertebr." iii. p. 374) that "in some instances the first premolar remains of small size when p. 2 and p. 3 are lost;" and Prof. Flower, commenting on the theory of reduction advanced by Prof. Owen, remarks ("Encycl. Brit," xv. p. 353) that "if this were invariably so, the labours of those who describe teeth would be greatly simplified; but there are unfortunately so many exceptions that a close scrutiny into the situation, relations, and development of a tooth may be required before its nature can be determined, and in some cases the evidence at our disposal is scarcely sufficient for the purpose."

Space will not admit of entering upon a criticism of the geological horizons adopted, which, so far as the Tertiaries of Europe are concerned, have been slightly modified by the author from the tables given by Gaudry, Boyd Dawkins, and Max Schlosser. We note, however, with satisfaction that he has rejected the prevalent notions as to the position of the Siwalik and Pikermi beds, referring the ossiferous strata of the former to the Upper and that of the latter to the Lower Pliocene—a view, if we mistake not, urged for some time past by Mr. W. T. Blanford. We could wish for a special note on the position of the Caylux and Quercy phosphorites of Central France, referred to the Upper Eocene; for the highly specialised character of the mammalian remains from these deposits appear to throw much doubt on their supposed age.

Where there is much to blame there is also much to praise; the descriptions appear to be in most cases excellent and carefully worked out, the subjects chosen for illustration well selected, and the woodcuts [illegible] well executed. We hope that this volume and [illegible] (which will probably include the remaining [illegible] fossil Mammalia represented in the collection) will together form but a "Prodromus" to a monograph [illegible] Mammalia by the same author, which, while equalling in comprehensiveness the best of the hitherto published catalogues issued by the Trustees of the British Museum, shall, however, surpass all of them in accuracy of description and in the number and excellence of its illustrations.

THE SELF-INSTRUCTOR IN NAVIGATION

The Self-Instructor in Navigation and Nautical Astronomy for the Local Marine Board Examinations and for Use at Sea. With numerous Examples, Illustrations, Diagrams, and Charts. By W. H. Rosser. Fifth and Thoroughly Revised Edition. (London: Simpkin and Sons, 1885.)

BOOKS of this character have presumably their use, and this particular one is neither worse nor better than many others which owe their being to the necessities of the examination room rather than to the wants of the practical navigator. Its table of contents is precisely according to the schedule of the Board of Trade, and though it is spoken of in the preface as "adequate for use at sea," Mr. Rosser has proved in other books that he knows it can be so considered only as an indirect compliment to the Board of Trade Examinations, which have been carefully devised so as to call for the greatest possible amount of cram and the smallest possible amount of real knowledge. The "Self-Instructor" has run through many editions, and no doubt answers the purpose of the author sufficiently well: it is, he says, essentially practical and not theoretical; though he omits to say this quality is to be understood as referring to what is wanted for examination, and that theoretical refers to any rational or intelligent mode of working. It is not Mr. Rosser's fault that the examination is laid down on such narrow and really unpractical lines; and what he has proposed to do he has done fairly well; though it would be well to expunge from future editions the symbol given to stand for the "observed distance between the sun's and moon's far limb"; more especially as the same symbol is to be used, as on p. 304, for a distance observed to the moon's near limb.

As a little matter of history, it may be remarked that the statement on p. 364, that the method of determining the latitude by the altitudes of two stars on the same hour-circle was originally given by Mr. Rob. Ball in the *Nautical Magazine* for 1874, is not quite accurate. Mr. Ball Bolt, in the article referred to, makes no claim of originality, but merely says that the problem may be new to many even expert calculators. In point of fact the method suggested itself to, and was taught and practised by, the writer of this notice in 1859, and was introduced by him into the examination papers of the Royal Naval College in 1866; since which time it has been frequently set as a theoretical question. In reality, it could not be so considered; for though it gives very good results and the observation is by no means a delicate one, the rough approximation to the interval of time [illegible]

sufficient, still the method is only available on a comparatively clear night; and though the same sights may possibly be also used for the determination of longitude, it will more commonly happen that the complete position may be satisfactorily determined by Sumner's method applied to two stars having a considerable difference in azimuth.

The pages in which Mr. Rosser treats of Sumner's method are of themselves sufficient to establish what has been already said as to the practical nature of the book. In an admirable monograph published two years ago, under the title of "Stellar Navigation," Mr. Rosser has shown himself alive to the very great value of this method of determining a ship's position, and to the necessity of shortening the calculation by the use of Sir William Thomson's special tables, or by Burdwood's and Davis's azimuth tables. But no remark in the "Self-Instructor" calls attention to this, and the problem is left, in its native nebulosity, in the form suitable to the questions of the examination room. The same might indeed be said of almost all other problems, which are given without any aid of the little artifices which, in practice on ship-board, render the computation quicker and easier. In saying this, however, we attach no blame to Mr. Rosser, unless he is for calling his book "practical," or "adapted for use at sea." The book is meant to meet the demands of the examinations; and for this, at least, it appears sufficiently well adapted.

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts. No notice is taken of anonymous communications.*

The Editor urgently requests correspondents to keep their letters as short as possible. The pressure on his space is so great that it is impossible otherwise to insure the appearance even of communications containing interesting and novel facts.]

The Cause of the Dissimilarity between the Faunas of the Mediterranean and Red Seas

THE republication by Mr. A. H. Cooke of the list of Testacea and Mollusca obtained by the late Mr. Robert MacAndrew during a dredging excursion (in 1869) in the Gulf of Suez,[1] adds data for comparison with that of the Mediterranean over the eastern part, and of which the late Mr. J. Gwyn Jeffreys has, amongst other writers, given an account.[2] The extreme dissimilarity in reference to the species will, upon such a comparison, impress the mind.[3] I propose briefly to sketch out the process by which this dissimilarity may be supposed to have been brought about.

Going back to the Eocene period, we know that the whole of the region bordering the Levant, and including large portions of the three continents, formed the bed of the ocean, and we may presume that a community of genera and species existed over the whole tract represented by those of the nummulite limestone of the Middle Eocene period.

During the Upper Eocene period there was a shallowing of the sea-bed in many places, and corresponding deepening in others, and thus the first division of the submerged area into deep and shallow basins would have been brought about with a marked influence on the animal and plant life; but the general features may not have been considerable.

It was during the succeeding Miocene period that the differentiation of the fauna and flora of the two seas really began. The observations on the geology of Northern Africa, Arabia, and Palestine by Zittel, Lartet, and others, leave little doubt that the Miocene period was one during which the main lines of the future lands and seas were marked out; and the absence of deposits belonging to this epoch (except a few scattered tracts formed of shallow-water and littoral beds) over the region referred to, leads to the conclusion that land-conditions prevailed very much where we now find them, and that the submerged areas of the Mediterranean and Red Seas were discovered by the Isthmus of Suez. It was during this period of elevation that the differentiation proceeded; the original forms of the Eocene period developing in each basin independently of one another, and becoming more divergent as time went on. The process seems to have been continued well into the Pliocene epoch, but at a time which may be indicated perhaps as "Newer Pliocene" there occurred a re-submergence of the land to the extent of 200 to 250 feet below the present level of the sea, marked by the occurrence of raised sea-beds containing shells, &c., of species still living in the adjoining waters, and of old coast-cliffs perforated by Pholas borings, like that discovered by Oscar Fraas in the cliffs of Jebel Mokattam, near Cairo, at an elevation of 220 feet above the surface of the Mediterranean, and recently described by Dr. Schweinfurth (*Zeitsch. d. deutschen geolog. Gesellschaft*, 1883). During this depression Africa became an island, and the waters of the two seas were united.

With this union of the Mediterranean and Red Seas there must have been brought about a certain commingling of the forms inhabiting their waters respectively, and hence it is somewhat surprising that there should at the present day be found such an almost entire dissimilarity as that already stated. The explanation, it seems to me, is to be found in the fact that the strait was, in its shallower portion, very shallow; and that consequently, except for the purely littoral and shallow forms of marine life, a commingling really did not take place to any great extent. To the north of Lake Timsah there occurs a ridge of ground called *El Guisr*, which rises 70 feet above the present sea-level, and another called *Tumah*, which rises 25 feet. These ridges would have caused a shallowing of the strait to the extent of their elevation, so that over the former ridge the depth of the strait would only have amounted to 180 feet or less during the greatest submergence. It is impossible to say whether these ridges are higher, or the contrary, than they were at that period; but it is a remarkable fact that the sub-fossil shells in the gravels to the south of Tumah are those of the Red Sea, and to the north those of the Mediterranean; other ridges, like that of Tel-el-Kebir, produced similar shallows. As a general result it is clear that the submersion of the isthmus during the later Pliocene period did not produce a general commingling of the forms of the two seas; and when ultimately the seas were again separated by the re-elevation of their beds, and the present isthmus established, those forms which may have passed across from sea to sea would succumb to the altered conditions of their environment. It can scarcely be doubted that the temperature of the water of the Red Sea differs considerably from that of the Mediterranean by several degrees, and the forms which belong to the former would perish in the latter, and *vice versâ*. It would be interesting to ascertain which of the two faunas more closely resembles that of the original Eocene stock.

Here, then, we have the remarkable zoological phenomenon of two perfectly distinct sets of marine forms originating in one stock only so far back as the Middle Eocene period, independently developing to such an extent that, at the present day, there are scarcely more than eighteen species (according to Prof. Issel) common to both. Now, if the beds of these two seas (the Levant and Red Sea) were to be elevated into land and their fossil contents studied by a geologist of the future, he would probably assert on the palæontological evidence that they belonged to two distinct periods of geological time! This is subject matter for reflection, at least for geologists of the present day. I may add that I have been induced to try and solve to my own satisfaction the problem here presented while engaged on a work containing the scientific observations and conclusions made during the recent expedition to Arabia Petræa in connection with the "Palestine Exploration Fund."

EDWARD HULL.

Hybridization among Salmonidæ

I PERCEIVE in NATURE (vol. xxxi. p. 563) that the "National Fish Culture Association" propose cross-breeding land-locked salmon and trout as proposed by Prof. Brown Goode in "Forest and Stream," August 7, 1884. Before doing so I would venture to direct their attention to a few points.

"Land-locked salmon" is admitted to be a race of the true *Salmo salar*, which from some cause having lost its migratory instinct, now lives in lakes, never migrating seawards, while its size is less than that of its sea-going relative. But as the two species are really the same, a cross between a land-locked salmon and a trout in fish-cultivation would be identical with a cross between a *Salmo salar* and a trout.

What then has been the result of attempting the latter cross at Howietown during the last few years? November 25, 1879, this was effected between salmon milt and Lochleven trout eggs; up to now all the offspring have been sterile, none have attempted to spring out of the ponds, and the largest fish among them last year, although in good condition, was only 16½ inches long. On December 24, 1881, this cross was again made, with similar results, the largest fish last winter being about 12 inches long. (Examples are in the South Kensington Museum). Sterility, I may remark, was anticipated from this cross, while it was supposed that such would remove the anadromous instinct, and these results have occurred, but as regards improvement in size, such has not, so far, proved a success.

A cross was made between a young salmon par and a Lochleven trout, on November 29, 1883, but the young succumbed to blue droopy of the sac. This cross was again tried November 14, 1884, when the par was a year older, and so far the young look well, but we can scarcely anticipate their proving fertile offspring. I say "scarcely," for we know that domestication eliminates sterility in some races of hybrids, and in this instance the par had been raised from eggs at Howietown; these have now grown into grilse without descending to the sea, and given eggs. Eggs thus furnished from Howietown-raised grilse have hatched, and several thousand young par are in the establishment, the future of which race will be an interesting study.

I think I am justified in advising that when crossing salmon with trout, not to select a parent from a river or lake, but, if possible, to obtain eggs or milt from a race of salmon which has been two or more generations in a semi-domesticated condition, as with such the probabilities of failure are considerably lessened, but, so far as I have witnessed, hybrids between salmon and trout have proved sterile and undersized.

Cheltenham FRANCIS DAY

Forms of Leaves

IN a recent issue of NATURE, in the discussion on the forms of leaves, Mr. Henslow seems to doubt the assertion of Sir John Lubbock that the holly produces prickly leaves on the lower branches, and smooth leaves without spines above; but this is a fact which may easily be verified in numerous localities (selected gardens varieties are of course not intended). I know of a large tree at Kew which altogether confirms the statement. The explanation, however, that the spines of the lower leaves may be produced to prevent animals from browsing on them, and that they are not developed on the upper branches because these are beyond the reach of animals, seems to me to require some modification, if not to be given up altogether, in this limited sense. It seems to me to admit of a much simpler explanation, namely, that it is an approximation—or reversion, if indeed the term be applicable—to the ancestral type. It is a well-known fact that in the embryonic stage of an organism the affinity with the ancestral type is best seen, and that in the mature stage the greatest amount of specialisation takes place; and, viewed in this light, the case of the holly does not appear to present much difficulty. A young seedling is seen to have very spiny leaves, but with increasing age the leaves becoming comparatively spineless. In the case of the furze we have the most overwhelming evidence that the spiny character has been developed to repel the attacks of herbivorous animals, and a young seedling is seen to have trifoliate leaves—like the laburnam—from which we infer that its ancestral type was spineless, and had trifoliate leaves. The large group of phyllodineous Acacias bear an equally unmistakable stamp of their origin in the bipinnate leaves which the seedlings at first produce. In most cases these leaves are very early superseded by phyllodes, but in *A. melanoxylon* the habit of producing true leaves is never quite lost. There is a large tree of this species about 40 feet high at Kew, at the south end of the Temperate House, close to the spiral staircase. It is thus in an admirable position for examination. At the base of this tree the leaves predominate over the phyllodes, but in ascending the staircase the proportion is seen to gradually diminish, till at the top of the tree—a few feet above the gallery—scarcely a true leaf is to be seen. Assuming the mature stage to be the more highly specialised, we have in the [illegible] precisely parallel case. This necessarily involves the [illegible] the ancestral type of the genus *Ilex* had spiny leaves; and it seems highly probable that the character was developed as a protection against the attacks of herbivorous animals. The possible objection which at first struck me was that some of the species have quite smooth leaves; but this has been removed by a search through the specimens in the Kew Herbarium. In the first place, species with spiny leaves occur in each [illegible] of distribution of the genus—in North and South America, in China and Japan, the Atlantic Islands, as well as Europe; in the second, although no seedling plants were found, there are three species which show very spiny leaves on lower branches and smooth leaves on the more mature flowering branches. These are *I. insignis* and *I. dipyrena*, from India, and *I. perado* from the Atlantic Islands. I have little doubt that seedlings of many species would present the spiny character if we could only see them. The presence of spines—the nerves being continued beyond the margin of the leaf—seems to indicate an arrested vascular over cellular tissue; a condition which is often [illegible] with increasing maturity or is not exhibited in the same [illegible] mena. In any case a severe pruning—or reduction of the [illegible] to be nourished—is followed by a temporary reversion to a more spiny character. If this explanation be the correct one, the question naturally arises, Why are the hollies losing the power of producing spiny leaves? rather than, Why [illegible] produce spiny leaves on its lower branches? The answer to the first query would perhaps be, Because they no longer need the protection afforded by the spines. To the second, [illegible] tinued habits are not often instantly laid aside.

Herbarium, Kew, April 18 K. A. [illegible]

Kite-Wire Suspended Anemometer Readings

HAVING lately made some observations with my [illegible] elevated, as above described, at heights above the ground considerably greater than those mentioned in my paper [illegible] British Association last year, I venture to think that a [illegible] two as to the main point at present under investigation, [illegible] general increase in the velocity with the altitude [illegible] between 600 and 1100 feet above the ground, may [illegible] to your readers.

Up to June last the greatest altitude reached by [illegible] meters was 646 feet. I have lately been able to [illegible] up to 1129 feet. Taking the average of seven of [illegible] the following values for the mean relative velocity of [illegible] heights:—

Height in feet above ground.	Velocity [illegible] feet per minute.
1070	2267
756	2165

When these values are inserted in the formula $\frac{V}{v} = \left(\frac{H}{h}\right)$ [illegible]

for the value of the exponent $x = 0{\cdot}17$, or a little [illegible] but when 500 feet—the elevation of the place [illegible] above the sea—are added to each elevation, we get $x = 0{\cdot}25$, almost exactly ¼, which is the value I deduced for [illegible] in NATURE (vol. xxv. p. 506), from a discussion of [illegible] cloud observations.

I would not at present lay much stress upon [illegible] cidence until I have investigated the ratio up to [illegible] 2000 feet or more, but I certainly think it [illegible] that the formula with this exponent represents the [illegible] of increase at heights over 1000 feet above sea-level.

E. DOUGLAS [illegible]

Temperature of the Body of Monotremes

I HAVE found the temperature of the body of [illegible] to be (average of three observations) 18·8 C. [illegible] *Ornithorhynchus paradoxus* (two observations) 24·4 C.[1]

These temperatures present a special interest, [illegible] with the mean temperature of the body of mammals [illegible] which is (after Dr. J. Davy's observations of [illegible] species) 38°·4 C.

the

ained
ings of the
received by the
erature of the air, which,
been 84°·5, fell to 81°·4, or
been at 7 a.m., and 0°·6 lower than
The amount of the temperature depres-
e to the withdrawal of the sun's heat was 3°·9;
d, corresponding with this lowering of the temperature, the relative humidity increased 5 per cent. during the eclipse.

The main interest of the observations, however, centres in the influence of the eclipse on the diurnal barometric curve. The diurnal march of the atmospheric pressure in these regions may well be classed among the most regularly recurring phenomena of terrestrial physics. From hourly observations made from April 25 to May 5 the mean at 10 a.m. was 29·957 inches, and at 2 p.m. 29·844 inches, the barometer thus falling in these four hours 0·113 inch. Between these hours, on May 6, the eclipse occurred, the total phase of the eclipse being from 11·32 to 11·37 a.m. On that day the barometric curve presented a form wholly different from what is daily observed in these regions. From 10·30 to 11·25 a.m. the barometer fell with a greater rapidity than the normal rate of fall, being at 11.20 a.m. 0·016 inch lower than the normal at that hour. Immediately thereafter a rapid and abnormal rise set in, the usual fall being arrested and replaced by an actual rise, so that while pressure at 11.20 a.m. was 29.927 inches, at 11.50 a.m. it was 29·940 inches. At 12.10 p.m. it was ·019 inch above the normal for that hour. Since the barometer was 0·016 inch lower than the normal at 11.20 a.m., and 0·019 inch higher at 12.10 p.m., it follows that the disturbance from the normal values during these fifty minutes occasioned by the eclipse amounted to 0·035 inch, being equal to nearly a third of the whole diurnal oscillation from the morning maximum to the afternoon minimum.

The time and manner of this abnormality is of special significance, inasmuch as it indicates a more rapid fall than the average during the first partial phase, when the sun's heat began to be cut off, and a rise above the average wholly exceptional after the close of the total phase, the maximum rise being delayed thirty-three minutes after the period of totality. An eclipse differs essentially from all other influences affecting the atmosphere, in that it cuts off the sun's heat from a restricted section of the earth's atmosphere extending from the surface to the extreme limits of the atmosphere, while from the air surrounding the shaded region the sun's heat is not cut off. Now, the observations showed that the first effect of the cutting off of the sun's rays and consequent reduction of the temperature, which no doubt extended through the whole height of the atmosphere, was to lower the pressure below the normal. This diminished tension was simply the direct result of the lowering of the temperature of the air over the region where the barometric observations were made.

Following this diminution of the pressure, an inflow of air towards the retreating path of the shadow set in, and pressure quickly rose above the normal of the hour, and as the sun's rays now heated the air with this excess thus temporarily accumulated over Caroline Island, pressure rose still further, till at thirty-three minutes after the close of the total phase it was 0·019 inch above the normal. Thereafter pressure fell with a corresponding rapidity during the next twenty minutes, at the close of which time it stood at the normal. The whole phases of the disturbance in the diurnal march of the pressure caused by the eclipse occupied two hours ending with 12.30 p.m. It is from their bearings on the theory of the diurnal oscillations of the barometer that Mr. Upton's observations must be regarded as of the highest importance (see "Encyclopædia Britannica," *Meteorology*, pp. 122 and 123).

Pointed attention is given in the report to the observations of the wind, which showed that, though the island is situated in the region usually included in the south-east trades, yet the direction of the wind was almost always noted as east or north-east, and was at no time observed to be from any other quarter than between north and east. Not a single observation during the time the expedition was on the island gave a direction south of east. The *Challenger* in this part of its cruise, during September, 1875, noted the same directions of the wind, and during the cruise to southward the north-east trades were not left till lat 13° S. was reached.

During the voyage from Callao, the *Hartford* sailed day after day in the region of the south-east trades, upon almost the same parallel of latitude, and with but few changes in the position of the sails, no steam being used. Since the conditions were so constant during the twenty-two days in which the vessel sailed in lat. 11° 5′ S. from long. 79° to 137° W., a tabulation of the hourly speed of the vessel day by day has been made from the ship's log. The mean values show a distinct increase in the evening, and a corresponding decrease in the morning, the maximum, 6·8 miles per hour, occurring at 10 p.m., and the minimum, 5·9 miles, at 10 a.m. With reference to the result, Mr. Upton remarks that, "It seems fair to attribute this to a diurnal variation in the wind's velocity. There is quite an unexpected regularity in the progression when we consider the approximate nature of the method. If not attributable to diurnal change in the wind itself, it yet indicates a diurnal change in the effect of the wind upon the sails, and is therefore of interest."

Report of observations made on the expedition to Caroline Island to erve the total solar eclipse of May 6, 1883, by Winslow Upton. (Washton, 1884.)

SIR WILLIAM THOMSON ON MOLECULAR DYNAMICS[1]

III.

BEFORE proceeding with new parts of this subject, I wish to say a few words about "fiddling while Rome is burning." Sir William Thomson writes to me that the expression was used while discussing some mathematical triviality, and he wishes to be relieved of the imputation

[1] Continued from p. 510.

of speaking disrespectfully of *anomalous dispersion*, which he says is quite as important as *double refraction*. I grant this, but my interpretation of his language when I heard the lecture was that so many possible ways had been shown of explaining anomalous dispersion that it was mere child's play (or fiddle-playing) to discuss it while the burning question of double refraction awaited explanation, upon which question seems to depend the whole safety of the wave-theory of light, that theory being in imminent danger of destruction therefrom.

I shall now give a brief account of the gyrostatic molecules, crude and improved. The crude one is a fly-wheel inside a massless shell. Here there is no gyrostatic action opposing a motion of translation, but only opposing a motion of rotation. This is the molecule which was stated to give the wrong kind of variation of magneto-optic rotation with variation of wave-length. The improved gyrostatic molecule (p. 320) consists of two fly-wheels on one axis. But the axis is cut in two in the middle between them, and the parts fitted together by a ball and cylinder joint. The other ends of the half axes are supported in ball-and-socket joints in the massless shell. So far as rotation of the shell is concerned, this acts like one gyrostat, the axis always remaining in one line. But if the shell be frictionless, the ether can only give translational movement to it, and the double gyrostat produces a gyrostatic effect when the molecule is accelerated in any direction except along the axis.

The special function of this molecule is to explain magneto-optic rotation of the plane of polarisation. The axis of the molecule is supposed to be the direction of the lines of force. It is required to be proved that, gyrostatic molecules being imbedded in the ether with their axes parallel and their directions of rotation the same, the velocity of propagation of a circular disturbance going with the gyrostat is greater than that of a circular disturbance in the opposite direction. With a steady propagation of circularly polarised light, the gyrostats will clearly execute a precessional motion. The theory of this motion is examined after the manner of Thomson and Tait's "Natural Philosophy" for a ray along the axes, and the gyrostatic effect is found to be equivalent to altering the effective density of the molecule, and so altering the velocity of propagation. Thus if v and v' are the velocities of propagation along the axis of rays polarised circularly in the two directions, it comes out that approximately

$$\frac{v'}{v} = 1 + h\,\frac{\omega}{\gamma},$$

where h is a constant depending on the form of the gyrostats, ω is the angular velocity of the precessional rotation of the gyrostats, and γ is the velocity of rotation of the gyrostats. This is a totally different law to the action of the *crude* gyrostatic molecule, and is in accordance with experiment.

If now we have *improved* gyrostatic molecules imbedded in the ether, their minute rotations will affect the velocity of propagation in the manner of crude molecules, but their translations will affect the velocity in the manner now elucidated. But observe that by diminishing the size of the molecules the influence of the rotational motion diminishes, but the influence of the translational motion remains the same (on the assumption that the angular gyrostatic velocity is kept the same and the ratio of mass of gyrostats to mass of molecule remains the same). Hence, if we have small enough molecules, the law which agrees with experiment alone holds. This is a very satisfactory state of affairs, and I believe it is the first time that Sir William Thomson's hint about this phenomenon, so long ago thrown out, has been developed.

There is still so much matter in the lectures that I have not touched upon that I am in some difficulty as to what the whole of the last lecture. This is of course impossible, but I will claim a little space for some remarks on Rankine's beautiful but futile attempt to get over the fatal difficulty of double refraction (p. 371):—

"Suppose here a massless rigid lining of no ... cavity in the luminiferous ether. Let there be a ... heavy molecule inside, with fluid around it. The ... thing is that this molecule, which only affects the ... inertia of the ether by adding its own mass to the ... mass of the ether, has isolotropy of inertia. Imagine the spherule (drawing on the board an oblate spheroid with axis vertical) moving first in a horizontal direction. The effective inertia of this sheath will be altered if it moves to and fro in a vertical direction, there being, by hypothesis, liquid between it and the ether. The density of this mass must be greater than the density of the ... that is all. If there is danger of its coming to the side ... the cavity, let there be springs to keep it in place, if ... like, but let its connection with the lining of the ... be in the main through fluid pressure. Then its effective inertia is different in different directions. This ... lining seems to hit off the very thing we wanted. Now comes Rankine's want of strength. He cut around the edges of it, and, I think, rather jumped at it, and ... down a wave-surface the same as Fresnel's, and said ... it came to that. But, alas! Stokes (long before ... Rayleigh suggested it) showed that it would give a ... ent surface from Fresnel's. Lord Rayleigh, in ... Rankine's suggestion, showed his strength where ... was not so strong in mathematical powers of ... with a difficult mathematical problem. Lord ... a man who grapples with a difficulty and sees how ... he can do with it. He puts it aside if he cannot ... but he never shirks it. Rankine was not a mathematician in that sense at all. Lord Rayleigh finds, not Fresnel's wave-surface, but a wave-surface differing from Fresnel's by certain terms appearing in reciprocals ... directly."

Now Stokes has shown that Huyghen's construction satisfies experiment with great accuracy, and hence Rankine's effort fails. The desperate condition of the wave-theory is shown by the words penned by Lord Rayleigh before he knew of Stokes's experiments (p. 272): "Should the verdict go against the view of the present paper, it is hard to see how any consistent theory is possible which shall embrace at once the laws of scattering, regular reflection and double refraction."

It appears, then, that after all the labour which has been expended upon the wave-theory of light, it fails absolutely, and, as it seems, hopelessly, in two points of primary importance. One is the extinction of the ... polarised by reflection; the other is double refraction. In other matters we have difficulties, but we can see possible means of escape. Here there seems to be ...

Before concluding this series of articles I wish to ... little more about the manner of their delivery. It is a rare experience for students to have the opportunity of studying the workings of a great mind while grappling with a problem. This is what occurred during the ... weeks of the Baltimore lectures. During the whole ... this period one or two ardent students were hunting ... references in the Peabody Library, &c., and literally ... Sir William Thomson's rooms with the results of ... searches, and Sir William generally read them ... He says (p. 76):—"An interminable number of ... have been brought to me, and in every one of them I have found something very important." Or at p. 78 he says:—"I got another quarter-hundredweight of ... on the subject. I have not yet read them all through. In this way he often came for the first time upon ... searches bearing on the question in hand. Thus on ... "I only found this morning that Lommel also ... to double refraction of light in crystals [with ... molecules]. The very problem I ...

against." Evidence is always cropping up that the author is in the habit of going farther into a subject by original mathematical analysis than by reading up other people's work. I will give some examples. Speaking of a reference by Rankine to cubic asymmetry, he says:—"I only came across this in Rankine two or three days ago. But I remember going through the same thing myself not long ago, and I said to Stokes—I always consulted my great authority, Stokes, whenever I got a chance—'Surely there may be such a thing found to exemplify this kind of asymmetry; would it not be likely to be found in crystals of the cubic class?' Stokes—he knew almost everything—instantly said: 'Oh, Sir David Brewster thought he had found it in cubic crystals, but there was an explanation that it seemed to be owing to the effect of the cleavage planes or the separation of the crystal into several crystalline laminæ'" (p. 158). Then again he says:—"I am ashamed to say that I never heard of anomalous dispersion until after I found it lurking in the formulas. I said to myself, 'These formulas would imply that, and I never heard of it;' and when I looked into the matter I found, to my shame, that a thing which had been known by others for eight or ten years I had not known until I found it in the dynamics" (p. 120). Once more we find:—"I was thinking about this, three days ago, and said to myself, 'There must be bright lines of reflection from bodies in which we have those molecules that can produce intense absorption. Speaking about it to Lord Rayleigh at breakfast, he informed me of this paper of Stokes's, and I looked and saw that what I had thought of was there. It was known perfectly well, but the molecule first discovered it to me. I am exceedingly interested about these things, since I am only beginning to find out what everybody else knew, such as anomalous dispersion, and those quasi colours, and so on" (p. 282).

The purely physical bent of the author's reasoning is well shown in speaking of Rankine's work at p. 270: "I do not think I would like to suggest that Rankine's molecular hypothesis is of very great importance. The title is of more importance than anything else in the work. Rankine was that kind of genius that his names were of enormous suggestiveness, but we cannot say that always of the substance. We cannot find a foundation for a great deal of his mathematical writings, and there is no explanation of his kind of matter. I never satisfy myself until I can make a mechanical model of a thing. If I can make a mechanical model, I can understand it. As long as I cannot make a mechanical model all the way through, I cannot understand; and that is why I cannot get[1] the electromagnetic theory. I firmly believe in an electromagnetic theory of light, and that, when we understand electricity and magnetism and light, we shall see them all together as part of a whole. But I want to understand light as well as I can without introducing things that we understand even less of. That is why I take plain dynamics. I can get a model in plain dynamics, I cannot in electromagnetics. But so soon as we have rotators to take the part of magnets and something imponderable to take the part of magnetism, and realise by experiment Maxwell's beautiful ideas of electric displacements, and so on, then we shall see electricity, magnetism, and light closely united and grounded in the same system."

The model of an electromagnetic ether described by Prof. Fitzgerald on March 28 to the Physical Society, founded on Clerk Maxwell's celebrated papers in the *Philosophical Magazine* in 1860 and 1861, goes a long way to clear away the objection raised by Sir William Thomson.

In reading these lectures, it must be remembered that they are uncorrected *verbatim* reports, and one is surprised at seeing that the matter is so continuous and readable. A considerable freshness is given by the conversational interludes and remarks, which would not perhaps have appeared in a written work. As mentioned before, Sir William spoke of the pressural wave as an animal; this was very happy, as he had just before called it the *bête noir* of the mathematicians. He says at p. 34:—"I do not like the words 'paradoxical phenomenon.' 'Curious phenomenon' or 'interesting phenomenon' would be better. There is no paradox in science. We may call it a *dynamox*, but not a *paradox*" At p. 115 he says:—The struggle of 1815 (that is not the same idea as *la grande guerre de* 1815) was, who was to rule the waves, Cauchy or Poisson?"

To many it will seem, after reading these lectures containing a review of what has been done and suggestions of what might be done, that certain facts are hopelessly irreconcilable with the wave-theory of light. Sir William Thomson has certainly not shirked a single difficulty, and perhaps has even made them look more glaring than is necessary. But, if this be an error, it is on the right side.

The reporter has introduced into the volume some doggerel rhymes read by a certain student of the lectures at a farewell dinner at Baltimore given by President Gilman:—

The Lament of the Twenty-one Coefficients at parting from each other and from their Esteem d Molecule

An æolotropic molecule was looking at the view,
Surrounded by his coefficients twenty-one or two,
And wondering whether he could make a sky of azure blue,
With plagiotatic *a b c* and thlipsinomic *Q*.

They looked like sand upon the shore with waves upon the sea,
But the waves were all too wilful and determined to be free;
And in spite of *n's* rigidity they never could agree
In becoming quite subservient to thlipsinomic *P*.

Then web-like coefficients and a loaded molecule,
With a noble wiggler at their head, worked hard as Haughton's mule;
But the waves all laughed, and said, "A wiggler, thinking he could rule
A wave, was nothing better than a sidelong, normal fool."

So the coefficients sighed, and gave a last tangential skew,
And *a* shook hands with *b* and *c*, and *S* and *T* and *U*,
And with a tear they parted; but they said they would be true
To their much-beloved wiggler and to thlipsinomic *Q*.

Signed, (*g*, *f*), A Cross Coefficient now Annulled

The social and scientific intercourse of these three weeks at Baltimore was an experience that will be forgotten by none of the twenty-one coefficients, and they all sympathised with Sir William Thomson in his concluding remarks at p. 289:—

"I am exceedingly sorry that our twenty-one coefficients are to be scattered, but, though scattered far and wide, I hope we will still be coefficients working together for the great cause we are all so much interested in. I would be most happy to look forward to another conference, and the one damper to that happiness is that this one is now to end, and we shall be compelled to look forward for a time. I hope only that we shall all meet again in some such way. I would say to those whose homes are on this side of the Atlantic, 'Come on the other side and I will welcome you heartily, and we may have more conferences.' Whether we have such a conference on this side or on the other side of the Atlantic again it will be a thing to look forward to—as this is to look back upon—as one of the most precious incidents I can possibly have. I suppose we must say farewell!" George Forbes

[1] These reports are generally quite *verbatim*, but I am sure Sir William Thomson is not responsible for this characteristic Americanism.—G. F.

THE SEMAPHORE AND ELECTRIC LIGHT AT SHANGHAI

THE European and American community occupying the so-called foreign concessions in Shanghai has lately adopted the electric light. The illustration given

below is the reproduction of a Chinese drawing representing the light and a semaphore with a time-ball in the French concession. It is taken from *La Nature*, and originally appeared in a Chinese illustrated journal called the *Hu-Aus*, which described the illustration in the following manner :—

"On the French concession, at the end of the settlements of the other foreign nations, a semaphore which marks the hour and the wind was erected last autumn. Every day at 10 o'clock a flag is hoisted which indicates the wind that is blowing on the sea at the mouth of the river. Every day at 11.45 a ball is raised to half-way, and five minutes before noon it is raised to the top. Precisely at noon it falls. In this way all the people of Shanghai can know the exact hour. The flags vary in form, in number, and in colour, according to the direction and force of the wind. Truly, it is a very good thing."

The illustration represents the semaphore to the left,

with the Chinese looking up at the ball which is about to be raised. The semaphore was erected on September 1, 1884, at a cost of 28,000 francs, by the French Municipal Council. It gives the hour at noon, and the force and direction of the winds at the mouth of the Yang-tsze-kiang. It is connected with the Zikawei Observatory, which receives the observations respecting the wind from Gutzlaff Island, at the mouth of the river, and which the director of the Observatory, Père Dechevrens, passes on by telephone to the assistant in Shanghai. The [illegible] is in direct connection with Zikawei. The wires [illegible] and lamps of the electric light are also noticeable [illegible] illustration. The light, which was set up last year, [illegible] for some reason not to be successful, and when the last mails left Shanghai the Municipal Council were in correspondence with the gas company with the object of coming to an arrangement for a return to lighting the streets with gas.

VARIABLE STARS

IN his stirring "Call to Friends of Astronomy" (*Schumacher's Jahrbuch*, 1844) to aid the advance of the science by taking up some definite department of work, Prof. Argelander, among other points for investigation, drew attention to the observation of variable stars as presenting a fascinating field of inquiry in which much valuable work might be done. Forty years have passed since this appeal was made. The list of eighteen stars visible in these latitudes then certainly known to be variable has grown to at least ten times the number, while a new "instrument of precision" has been placed in the hands of the observer in the form of the spectroscope, which has largely increased his powers. But, after all, it must be acknowledged that we are still greatly in ignorance of the causes which immediately underlie the striking phenomena which are presented to our view.

In taking a rapid glance at some of the phenomena with which we have to deal, it may be convenient [illegible]

pt some form of classification of variable stars. The owing arrangement suggested by Prof. Pickering will our purpose; but at the same time it should be re-rked that links of association may sometimes be dis-ered between individual members of different classes espect of some of their characteristics. It is probable, that after all some stars must remain unclassed.

Class I. Temporary stars, or those which shine out denly, sometimes with great brilliancy, and gradually away. Examples: Tycho Brahe's star of 1572; star in Corona 1866.

Class II. Long-period variables, or those undergoing t variations of light, the changes recurring in periods everal months. Examples: *o* Ceti and γ Cygni.

Class III. Stars undergoing slight changes according aws as yet unknown. Examples: *a* Orionis and *a* siopeiæ.

Class IV. Short-period variables, or stars whose light ntinually varying, but the changes are repeated with t regularity in a period not exceeding a few days. mples: β Lyræ and δ Cephei.

Class V. Algol stars, or stars which, for the greater ion of the time, undergo no change in light, but every days suffer a remarkable diminution in light for a hours. Examples: β Persei (Algol) and S Cancri."

he temporary or new stars form a remarkable class of , which blaze unexpectedly into view and then ually decline. A striking object of this class was ho Brahe's star of 1572, which attained such a ancy as to be visible by day. It was not, however, he year 1866 that a clue was found to the probable re of these outbursts, when the examination of the trum of the new star which appeared in Corona alis in May of that year by Dr. Huggins suggested iew that in these cases the outburst is due to the ation of large volumes of gas, which enwraps the star flaming envelope which gradually burns itself out.

he most recently-observed star of this type has a ous history. On September 24, 1876, the late Dr. nidt discovered, in the constellation Cygnus, a new of the 3rd magnitude, which soon began to fade. the star T Coronæ it had a double spectrum. In ember, 1877, when the star had fallen to 10·5 mag., xamination of its spectrum at the Earl of Crawford's rvatory showed that the continuous spectrum had ppeared and that the star's light was monochromatic. act, to all appearance the star had become a minute etary nebula!

he distinguishing characteristic of stars of this type, ely the temporary character of their phenomena, ply marks them off from the variables of all the other es, in which the changes recur with greater or less larity. A connecting-link, however, may perhaps be d in the remarkable variable, U Geminorum, dis-red by Mr. Hind in 1855. It has a very irregular d, which ranges between 7·0 and 12·6 days, during t three-quarters or more of which time it remains uating about a minimum magnitude of 14·5. It rises lly to maximum (at the maximum of February, 1877, e rate of over three magnitudes in twenty-four hours), then, at first gradually and then more rapidly, falls ninimum again. Its colour has generally been de-ed as bluish-white (though it has been noted ruddy), a curious, ill-defined or hazy appearance has been ed by several observers which would suggest the bility of bright lines being found in its spectrum, a cion which has not as yet been confirmed.

ss II. includes by far the greater number of known ble stars. Many of these are highly coloured, ing tints of red or orange of various degrees of sity, and among them are to be found stars having anded spectra of Secchi's types III. and IV. The arity with which they go through their changes is of us degrees, and varies even in the same star at different times, while in some cases there is evidenced a tendency to form subsidiary maxima or minima on the main light curve. In some instances also the magnitude touched by the same star at maximum or minimum is subject to fluctuations, and this apparently quite independently of the degree of regularity with which the changes are gone through in respect of time. In two stars at least of this class—Mira Ceti and R Geminorum—bright lines have been observed in their spectra.

It is perhaps to be regretted that a separate class has not been formed for variable stars having a double period, with two equal or nearly equal maxima and two unequal minima, of which β Lyræ is the type. A star of this order, with a period of about 70 days, R Sagittæ, included in Class II. (though with an expression of doubt) in Prof. Pickering's list, seems to call for special remark. It was discovered by Mr. Baxendell in 1859, and his observations have shown first the approach to equality and then the reversal of the principal and secondary minima. The equalisation of the minima was also observed by Prof. Schönfeld, and their reversal by Mr. Chandler in America. The phenomenon thus exhibited is a remarkable one, though perhaps not unique, as something similar appears to have been noticed by Prof. Argelander and Prof. Schönfeld in the case of R Scuti.

Turning to Class III., a point should be mentioned in regard to one of the examples of the class *a* Orionis. Observing the star in March, 1866, Dr. Huggins noticed that "a group of lines and shading, as if of fine lines" had disappeared from its spectrum, the star at the time being at its maximum brilliancy. Six years later, however, Dr. Vogel, at Bothkamp, failed to detect any change of this character.

Passing to Class IV. we have, in one of the examples, β Lyræ, a star presenting points of singular interest. As has been already mentioned, its period of 12·9 days is a double one, with two equal maxima and two unequal minima, and Herr E. von Gothard, of the Herény Observatory, has discovered that its spectrum is also variable. Herr von Gothard has also observed the D_3 line (showing that Helium has a home in other suns than ours), and the lines of hydrogen as bright lines, and has further (*Astr. Nach.*, No. 2651) found them to vary in intensity in a period of about seven days. Further observation is required before any decided opinion can be expressed as to the relation between the variation of the spectrum and the variation of the star's light, but a comparison of Herr von Gothard's observations with the predictions of an ephemeris seems to suggest (though the evidence is not quite conclusive) that the bright lines are at their brightest when the star is near a minimum.

The stars of Class V., of which Algol is an example, form a group of variables of a well-marked type. The general features of their changes are fairly represented by the supposition of an eclipsing satellite. But in the case of U Cephei, a star of the group discovered a few years ago by Ceraski, a new feature is introduced which somewhat complicates the theory. Its period has been shown with some degree of probability to be a double one, with slightly unequal minima. Another curious fact which has been observed in regard to the star is that, as it falls below the 8th magnitude, its light becomes decidedly ruddy (indicating absorption as well as eclipse?), the ruddy colour being lost as the star rises to the 8th magnitude again, when it regains its ordinary brilliant bluish-white hue. It is only fair to remark that in Prof. Pickering's view the suggestion as to the duplicity of the star's period should be at present received with caution.

This brief review will suffice to show that any attempt to answer the question—What is a variable star?—involves the examination of a multiplicity of phenomena. At the same time, the causes presumably at work may be grouped broadly under two heads—geometric and chemico-physical. We have seen that in the case of the

temporary stars we have grounds for looking to the *latter*, while in the case of stars of the Algol group we have reasons for looking to the *former*, as a more or less probable cause of the changes we observe. While in β Lyræ we see that physical changes apparently accompany, if they are not connected with the cause of, the light-variation. Is it to geometric or to chemico-physical causes that we are to look as the key to the explanation of the phenomena in other groups, say of the large group of Class II.? A few considerations will show the grave difficulties we have to meet. A difference of from five to seven magnitudes between the points touched by the star at maximum and minimum is to be found in the case of many members of Class II. Now, taking the magnitude scale at present generally adopted, having a light-ratio of 2·512, a range of five magnitudes would correspond to a difference of light-intensity in the proportion of 100 to 1, while if the range is extended to seven magnitudes, the star's light-intensity at maximum would bear to its light-intensity at minimum a ratio of 630 to 1. These wide differences of intensity of radiation are sufficiently startling if they are supposed to occur only once in a while, as in the case of the temporary stars. What are we to say of them if we are to suppose them to occur over and over and over again, in periods of from 150 to 600 days? The subject was discussed in these columns some few years ago, and the difficulties presented were felt to be so serious as to make it hard to accept a theory of this kind as offering a probable explanation of the facts of these stars are to be regarded as suns in the usual sense of the term, though less difficulty might be felt if we could look on them, not as suns in our sense at all, but as small bodies. In this case they would be relatively near to us, and would have a measurable parallax. An inquiry in this direction might prove fruitful. As compared with this theory, the theory that the changes of light may be supposed due to periodic obscurations by bodies or groups of bodies revolving around the variable, presents less formidable objections, though it has, of course, difficulties of its own. A few months ago one of our first authorities on the subject penned the words: "No theory has yet been advanced that will account satisfactorily for the ordinary phenomena of variable stars." It is possible that we must look forward to a future of more or less lengthened patient research before theoretic views can be announced which shall be anything much better than "guesses at truth."

It is, then, to further work that we must look for further progress, and the recent discoveries in regard to β Lyræ indicate one direction at least in which research should be made. Is it not possible that some valuable results might be obtained if the spectra of a selected list of variable stars were to be carefully studied with one of our largest telescopes — the several spectroscopic results being co-ordinated with the corresponding position of the star in its light-curve as fixed by a careful determination of its magnitude? In the discovery of new variables, the determination of their periods and range of variation, and of the general characteristics of their light-curves, good work may be done with instruments of very moderate dimensions; but for all but the brighter stars the spectra are too faint to be adequately treated but by instruments of the largest size.

Whether by this means any satisfactory results should be obtained or no, it is evident that in the study of variable stars a point has been reached whence, in order to secure any further advance, it seems needful by some means or other to endeavour to take a new departure.

THE LATE EARL OF SELKIRK

ON Saturday, April 11, 1885, Dunbar James Douglas, sixth and last Earl of Selkirk died, after a short illness, at St. Mary's Isle, Kircudbright; had he lived till the 22nd of the month he would have completed his seventy-sixth year. His death, though it occurred at a ripe age, has proved a sudden and unexpected blow to those who hoped that many years of life might yet be in store to one upon whose spare and still vigorous frame [illegible] as yet apparently made but little impression, and whose mental and physical energy alike gave promise of a long prolonged period of utility. Those who so recently saw him in even more than his wonted health can scarcely realise the fact that he has succumbed, like many others to the evil influences of the treacherous and fickle winds which for some time swept over our islands, and terminated his valuable life after a short illness of only three weeks. How much he is regretted, how much he will be missed, it is impossible to say; for the measure of one so gifted and so good is an irreparable loss, and will be felt more and more as time progresses, whose the genial influence of his life and example had been.

Elsewhere have been described his ancient lineage, his connection with various great families of Nobles, his political opinions, his public life, the high offices filled in the State and in his county, the characteristic personal character which marked his whole life; his education at Eton, his success at Oxford, his travels and explorations in almost every quarter of the globe, the harvest of experience he so assiduously collected and carefully and accurately remembered; his thoughtful, unselfish nature, so loyal, so considerate of others, especially of the weak; so firm in assertion of all that he believed to be right, so excellent in all relations of public, private, and domestic life, so true a friend, so mindful of all whom he did or tried to do him the slightest service — all of which may some day be told again in detail, but much of which we dwelt on here in this brief notice, which would overlook rather the side of his nature which turned towards others and took so keen an interest in its progress and welfare, he himself being no mean contributor to its annals. Those who, like the writer, have had the privilege of long association with him, in the field, on the moor, in private life, and by the evening fireside, and have listened to his instructive conversation on many subjects connected with natural science, history, geography and biography, must have felt the satisfaction which arises from communion with one whose wisdom and experience seldom led him who enunciated no crude theory, made no hasty generalisation on imperfect or insufficient data, and whose judgment was tempered, calm and reasonable in all matters submitted to it for decision, must feel that by his death, science too has sustained a serious loss.

Lord Selkirk's great erudition and knowledge of man and nature were not derived merely from books. He was, indeed, a great reader, whose memory retained with extraordinary tenacity all the details even to minute particulars of that which he read; his vast amount of information were the result of much travel and much physical science. Few, indeed, had travelled so far, seen so much, or with such intelligent appreciation of what they did observe.

His mind was of a truly scientific mould, and willing nothing on insufficient or imperfect evidence; in all that was calculated to extend the limits of science was unbounded; but of all its departments, geology seemed to attract him most: he was a Fellow of the Geological Society, a frequent attendant at its meetings, and a contributor to its proceedings. One paper, "Sea-water Level Marks on the Coast of Sussex," read before the Society in 1867, was of much interest, and shows how closely he had studied that important subject. He was also a Fellow of the Royal Society, and took much interest in its proceedings, but deafness which affected him early in life and increased with age prevented him from taking an active part in the discussions of the learned societies, or in the debates in the House of Lords, and to a certain extent, therefore, [illegible]

aring in, though it in no way diminished the keen
he felt in their deliberations.

brary in his beautiful and ancient home contained
rks on science, literature, and art, but the great
se of knowledge was his own brain, and from this
ever delighted to contribute for the instruction
sement of his friends. All this, alas, has come

rroundings overlooking the sea, but his memory
be everywhere preserved in grateful recollection
iends and countrymen. J. F.

RORAIMA

kindness of Sir Joseph Hooker we are able to give
he illustrations relating to Roraima taken by Mr.
n during his recent successful expedition (aided
supplied by the British Association and Royal
hical Society) to the top of the previously un-
ountain. The following extracts from the paper
Monday at the Royal Geographical Society, by
. Perkin, who accompanied Mr. Im Thurn, will
e idea of the work and results of the expedi-

t of December, our first day in Brazilian terri-
camped to the south-west of, and quite close to
a splendid mountain towering above the general
he table-land some 3000 or 4000 feet, with bold,
lines ending in a well-defined peak, on its south
from forest, the savannah continuing quite up
mit, though densely wooded on its north-north-
north-west.

lofty range of hills some 3600 feet high we had a
view of Waetipu, Roraima, Kukenam, Marima,
mall mountains near Waetipu, named Hormi
reepa; the curious square, flat tops of Roraima
enam, with their dark, precipitous cliffs, adding
nd peculiar effect to the whole landscape. On
2 we arrived at Toroikire or Ipelemonta, an
village of four houses situated on the left bank
apu river.

ew from here is magnificent, as the village is
st in front of Roraima, giving a sight also of
; it is situated on a high hill 3751 feet above
but is dwarfed by the gigantic walls of rock
oraima being about four, and Kukenam about
s from it. Each mountain seems like a huge
ble fortress, built on a mountain-top 7000 feet
walls from 1200 to 1800 feet in height.

rtion of Roraima facing Teroota is four miles
of Kukenam about the same. In wet weather
mits are wrapped in dark clouds, and after the
er and the clouds have dispersed the water can
asting itself over the cliffs in splendid falls that
eing seen can be at all imagined. At a distance
five miles they look like delicate white threads
e dark background of sandstone rock.

o mountains are separated by a wide gorge, and
uds of dense white mist accumulate, and gradu-
ing up as the day advances, enshroud their sum-
ething after the manner of the "table-cloth" of
ountain.

ief difficulty Mr. Im Thurn apprehended was
dampness of the spot, as he feared he would be
dry the sheets of botanical paper used to pre-
specimens of plants he obtained, but by means
fire kept burning night and day this was easily
vented.

on this first visit of ours to the upper portion of
we saw on the face of the cliff itself a ledge of
ning up from the tree-covered portion of the
ower portion of the mountain to its summit; it
appeared to us extremely easy to climb, except in two places: the first where the bush that covered the ledge appeared to end suddenly, leaving the cliff bare and naked, and giving the ledge the appearance of being interrupted, and consequently impassable; and in the second place where a watercall from the summit falls on the ledge and has cut a gap in it, so that there seems to be a deep, wide hole, which it would take great trouble to bridge over. But on the whole it seemed so easy to climb the mountain here that we concluded there must be some insuperable difficulty of which we were not aware, for other travellers who had visited the mountain had stayed near this ledge, though, except Mr. Whitely, none of them attempted it, most of them having had to turn back soon after their arrival, owing to want of provisions, which latter contingency Mr. Im Thurn had particularly guarded against, and enabled us to stay some time and to make several excursions over the mountain-sides.

The north-east and west sides of Roraima are forest-covered, but on the south and south-west it is for the most part devoid of trees until a height of 5890 feet is reached, and from here up to the cliff-face the slope becomes far more steep and is covered by a thick, dense undergrowth: there are very few large trees, and even they are small when compared with the giant vegetation of the forests we had passed through.

Teroota village lies, so to speak, at the foot of the mountain, though the cliff portion is about four miles distant. Between Teroota Hill and Roraima flows the Kukenam river, which rises in Kukenam Mountain and descends from the summit in a splendid fall of about 1300 feet.

From the Kukenam river Roraima on its south-western side slopes up at an angle of about 20° to 4500 feet, and then at 30° to the commencement of the forest-covered portion to 5890 feet; from here to the cliff-face the incline is 15° steeper to about 7200 feet, and the remainder is cliff. At about 5600 feet we found a large piece of swampy ground filled with most exquisite varieties of orchids and ferns, and also the *Utricularia Humboldtii*, which grows to greater perfection here than on the Kaieteur savannah. Here also we found the Heliamphora or pitcher-plant, whose cup-shaped leaves were full of water; it bears a delicate white flower without smell.

We returned the same day, December 5, to Teroota, after our visit to Siedl.

We reascended the mountain on Sunday, December 7, and built our houses, one for ourselves and one for the men, at an altitude of 5405 feet above sea-level, close to Siedl's hut.

On the 10th, with Mr. Siedl, we went up a path cut by a Mr. Whitely in 1883, to the face of the cliff, and on our way, at 6410 feet, found a lovely flowering plant, the *Leiothamnus Elisabethæ*, of Schomburgk; it has deep carmine star-shaped flowers, with a white star centre, the points of which radiate down the petals. At 6841 feet we rediscovered another exquisite flower, first found by Richard Schomburgk, an Utricularia, with a large deep crimson blossom. The plant grows on the branches of trees, and is about 2 to 3 inches in height; the bloom, when but, completely hides the stalk, and is about an inch and a quarter long, by half an inch wide; sometimes there are two flowers on the same plant, but usually only one. The appearance of one of these bright blossoms on the sombre tree-branches has a most peculiar effect, and one's admiration is divided between the brightness of the flower and the wonderful energy of the tiny plant that produces it. Pursuing our way we reached the cliff at 12 o'clock, nearly three hours from the start, the way being extremely rough and steep, over root and trunks of trees, and bare rocks; at times we could hear water running among the stones under our feet.

FIG. 3.—Scene on top of Roraima.

obscured by the intervening bush, it seemed y of ascent.

ight we reached this day was 7350 feet, deter- boiling-point thermometer, and it took us three -quarter hours to return to our hut, a distance of and a half miles, as we frequently stopped to rns and other plants on our way.

11th we ordered the Arecunas to cut a path to f the ledge from the edge of the savannah, and if continue it as far as the summit. After a day's work they returned, saying they had finished the road, but we afterwards found they had left off from fear of Makunaima, the great spirit, just at the point where the ledge joins the upper sloping portion of the mountain. This was on the 14th, when we reached 7756 feet above sea-level, and found our way suddenly barred by a precipice of 120 feet. A heavy mist, too, arose, and it became bitterly cold, with the rain falling in torrents, which rendered our return journey dangerous, and the path slippery and muddy.

The next few days were occupied in surveying the country around the mountain and preserving plants; it was still too wet and slippery to enable us to make any further attempt on the mountain, but, learning from Simon, the Arecuna chief of Toroikng, that the rainy season was about setting in, we determined to make use of the first fine morning we might have; and on December 18, which dawned most auspiciously for us, we left our house after an early breakfast at 7 a.m., reaching the cliff at 8.30, where we waited for about half an hour, and then set forward along the ledge, the path keeping much the same the whole way over rocks and roots and trunks of trees, and sometimes along the slippery leaning stems of the trees, using our hands and knees for some portion of the way.

The Arecunas we had with us hung back when we got thus far, and for a long while would not proceed, until, by dint of persuasion and the promise of a taste of ardent spirits, we prevailed on them to accompany us; we had, however, to send one of the men from the Pomeron, a half Negro, half Indian, to go first and lead the way, cutting a path as he went on. In this way we reached the waterfall, which to our great surprise we found extremely easy to pass, as the ledge was not cut away by the action of the water falling on it, and fortunately there was very little water coming over, being more like a very heavy shower, which wet us to the skin immediately. The foothold around the spot was extremely precarious, being worn quite smooth and slippery by the constant moisture and falling water.

From this fall to the top the last portion of the ledge slopes at an angle of 30°, and is in places quite twenty or more yards in width; it is covered by a dense growth of moss, and in spots tall coarse grass, which gives way here and there to flowering plants and small shrubs. Of the flowers one in particular, a species of heath, took our fancy by its dark pink blossoms of six petals, about the size of a halfpenny, which lay in quantities along our path.

So occupied were we in securing each new treasure that we had almost gained the top before being aware of it, for near the summit the ledge loses its steepness and is, so to speak, merged into the top itself.

A curious sight met our eager gaze as we passed the boundary line of the unknown—on all sides were grouped rocks of every shape unimaginable, weird, strange, and fantastic, first a row of huge oblong stones that looked like rude cannon placed there to guard the approach; further on another rock like a giant's umbrella on a short thick stem of about four or five feet in height, and others like miniature castles and ruins of old churches, leaning so much that had they not been solidly connected portions of the enormous sandstone bed, they would have fallen. We saw no lake, however, but several pools of water here and there. The vegetation on the summit was extremely scanty and insignificant. There being no trees, only small bushes from three to six feet in height, growing at long intervals and, with the exception of a few scrubby orchids, two species of thick-leaved ferns and a variety of the red Utricularia from below, there was no other plant there, owing, no doubt, to the absence of soil; for it is not possible for earth to collect on the summit, as it would be almost immediately carried over by the rain-water which finds its way over the edge of the enormous cliff

soon after it has fallen in most splendid waterfalls, some of which have a clear fall of 1500 feet.

We had no sooner accomplished the ascent than an impenetrable cloud of mist enveloped the whole of the upper part of the mountain, entirely obscuring the view, and rendering it difficult to see beyond forty or fifty yards in any one direction, and putting a limit to our wanderings.

After boiling the thermometer, which registered 197° F., the average of five readings, and gave the height (allowing for difference of temperature from sea-level) as 8600 feet, we returned to our hut, but not before I had tried with true British instinct to carve my initials as a memento of our visit; but I found the rock far too hard to permit of this, and had to content myself with leaving an advertisement torn from a newspaper of Messrs. Pears' soap and Madame Patti's testimony of its suitability for the hands and complexion.

In conclusion, I beg to present the Society with a few samples of rock and rounded pebbles, which I obtained in the course of our journey up the mountain. I have been told they lead to no very definite conclusion in a geological sense, as they seem to belong to no particular geological epoch, but are apparently agglomerations of deposits from various causes.

No fossils have been found, but several of these smooth pebbles which I found imbedded in the living rock on the summit point to its having been submerged at some long-passed time, but whether this huge mass has been obtruded by volcanic action, or the cliff has been bared of its at one time circumjacent soil by glacial or aqueous action, I leave for those skilled in geology to discuss, and shall be happy to give any further information that may lead to a more definite conclusion as regards the formation and age of the mountain.

One word more and I have finished: it is to again remind you that the whole success of the expedition is due to Mr. Im Thurn's excellent management and indefatigable zeal, as well as his intimate knowledge of the Indian character; and if my short notes have aroused your interest in Mount Roraima, I must ask you to accord a larger portion of the same to his complete and detailed report, which I have no doubt will ere long arrive.

NOTES

It is well known to all acquainted with the British Museum, that the staff of the Zoological Department is very insufficient for the needs of so large a collection. In the vast subject of entomology especially the number of assistants is quite out of proportion to the mass of material necessarily accumulating with the advance of geographical exploration. We are glad to learn that a step towards remedying this state of things is about to be taken by the addition to the staff of an assistant, to be specially engaged upon the collection of Coleoptera. The conditions upon which the appointment will be filled up are announced in our advertising columns.

There seems to be at last some chance of the great Hume collection being received by the nation, as the British Museum has sent Mr. Bowdler Sharpe to Simla to pack and despatch the collection to England. Mr. Sharpe started by the last mail viâ Brindisi, and expects to be absent from England about four months.

Dr. Benjamin Apthorp Gould is to return to the United States very soon from South America, where he has recently completed the great works upon which he has been engaged for so long at the Observatory of Cordoba. His fellow-citizens of Boston, *Science* states, propose to give him a reception and a dinner on his return.

On May 13 a statue of Linnæus will be publicly unveiled at Stockholm. The day will be the 179th anniversary of his birth.

Reports from Japan state that grave fears were entertained of an outbreak of the long quiescent volcano Fusiyama, and that "officials had been sent to investigate the matter. The people living in the neighbourhood believed an eruption to be imminent, because, while the snow on the mountain had begun to melt two months before the usual time, all the wells near it became dry, and difficulty was experienced in procuring water. The phenomenon is considered the more remarkable from the fact that the winter has been unusually cold, and that the mass of the snow remains hard, the part nearest the ground being the first to give way.

Intelligence has been received in Amsterdam from Java of the eruption of the Semiroo mountain, the largest and most active of the Javanese volcanoes, situated on the confines of the Passoerean and Probolingo residencies. No mention is made of any loss of life having occurred.

Prof. Forel, of Geneva, has sent us an account of an earthquake observed in Switzerland on April 13 last. It was composed of a preliminary shock at Neufchâtel between 9 and 10 o'clock, of a principal or great shock at 11.23 a.m., and of a succeeding shock observed at Lausanne and Geneva at 5.0 p.m. The principal shock disturbed a considerable area. It was felt in the district bounded by Geneva, Saint-Cergues, the Joux valley, Neufchâtel, Soucebos, Aarau, Schwyz, Interlaken, the Bernese Alps, Bex, and the Lake of Geneva. The absence of reports from the other cantons, Valais in particular, will extend still more the area of disturbance, which already embraces a district 220 kilometres long by 100 broad, representing a superficial area of more than 20,000 kilometres. The area of disturbed surface is parallel to the chain of the Alps; in seismological classification this earthquake would therefore be placed under the classification of longitudinal earthquakes. Over the disturbed area the shock was felt unequally. The inhabitants of the cantons of Vaud and Neuchatel, the district which Prof. Forel is appointed to study, numerous and precise observations were received from Enhaut, Ormonts, the Rhone valley, the north shore of the Lake of Geneva, from Villeneuve to Monges, from Les Avants, Gingnis, Saint-Cergues, l'Orient de l'Orbe, Neufchâtel, Soucebos, &c., while none at all came from the valley of Joux, the valley of the Thièle, nor from Gros du Vaud. It would seem that the centre of the district remained quiet, while the borders were disturbed. The intensity of the shock was great when one approached the centre, which was probably the region of the Haut Simmenthal. There some damage was effected to the walls of houses; it is even said that rocks were precipitated from hills. This would represent a shock No. 8 in the scale which represents the intensity of earthquakes in six terms. In Prof. Forel's district the earthquake had very little violence. The shock had three undulations, with some seconds between each. In general the direction of the oscillations was indicated as parallel to the meridian, from north to south or according to the localities, as coming from north-east or south-west. A subterranean sound was heard in several places.

At the conclusion of an article in a recent number of [illegible] on the Andalusian earthquake, Herr Willkomm refers to previous earthquakes observed in Southern Spain; he shows that of Christmas day last is the greatest and most frightful of them all in the historical period, it is by no means [illegible] other respects. The provinces of the kingdom of Granada, [illegible] of the kingdom of Murcia to the west of this latter, and the province of Alicante belonging to the old kingdom of Valencia have frequently been visited by earthquakes. At Cape [illegible]

ear passes without one. Judging from past shocks, nd the neighbourhood of Torrevieja and Guardamar h of Alicante, are the two main earthquake centres. ast the shocks extend along the coast as far as Malaga. iolent occurred in 1518 and 1829. On November 9, 829, the towns of Guardamar and Torrevieja were nto heaps of ruins. Malaga has been visited by earth- times during the past century—viz. 1775 and 1777 : 10, 1790 ; January, February, and August, 1804, and 1841. In 1802, from January 17 to February 6, there ted shocks at Torre la Mula and Torrevieja ; on July Cartagena, Murcia, and Alicante (over 200 shocks in hours) ; on April 27, 1826, and until July of the innumerable shocks in and around Granada. The lation of Granada left the town and camped in the ilarly for many other places in Southern Spain. If be added the numerous earthquakes on the west of la, with centre at Lisbon, it will be clear that, next other part of Europe is so frequently visited by as the south and west of the Iberian peninsula.

NOTT, a missionary in Madagascar, writes from o *Cosmos* to report that on February 25, after a lone, the coast of Madagascar, near Tamatave, was h pumice-stone and dust, in all probability, says , from the Krakatoa eruption. On March 28, 1884, niece was found on the coast of Réunion. Sub- in the middle of May, the same phenomenon was Mayotte, in the Mozambique Channel ; and in of last year it was noticed at Tamatave. Crystals were mixed with the amorphous matter. The generally small, the edges being worn round by A very few were of a pale reddish colour. Accord- course of the currents in the Indian Ocean these been carried from the Straits of Sunda down to the degrees of south latitude in a south-westerly direc- rce they reached Madagascar, and the adjacent ough the agency of the equatorial current and the The probability that this pumice is that of the ruption is supported by the following facts: the rigate *Princesse*, passing the Straits of Sunda on 22, 1883, crossed large banks of pumice, and enc ght smaller ones until January 10, 1884, when she ° S. lat., and 66° 8' E. long. The average speed of is stated to have been fifteen miles per day. Sub- n April 13, 1884, the French war-ship *Bourayne* of this pumice floating off the coast of Madagascar, lat., and 48°2' E. long. The circumstances under pumice reached the Malagasy coast are specially o ethnologists, as they afford a new proof of the f human migrations to considerable distances. They some support to the theory that the Hovas of are of Malay descent.

rid Correspondent of the *Standard* writes that ors in Valencia have been making numerous experi- inoculating adults and children with the choleraic faith of the local physicians and of persons of all these experiments is so great that in one afternoon were inoculated. The Scolapian Fathers brought all also for this preventive vaccination against cholera. I must say the same phenomena have been observed ved in similar experiments in France last year during e. A commission of Madrid doctors has been sent the experiments.

cutive Council of the forthcoming International In- hibition at South Kensington has issued a most useful railway-guide and route-book, for the use of intending visitors. The district included is about forty miles in every direction around London, and the book gives for each station the number of trains daily, the fares, the average time occupied on the journey, the points at which to change for connection with the Exhibition, and the last two trains each day. It will be of great use to those numerous visitors who are not acquainted with the readiest and most convenient methods of getting from South Kensington to other parts of the metropolis and its suburbs.

WE have received the second edition of Marion's "Guide to Photography," the first edition of which we noticed on its appearance. The text contains various additions, needed to bring it abreast of the latest photographic improvements.

WE have received the Report of the Mason Science College, Birmingham, for the year ending "Founder's Day," February 23, 1885. The appeal issued last year for an additional endowment fund for scholarships and exhibitions, additions to the teaching staff, &c., has been met by subscriptions amounting to nearly 5000*l*. The free lectures to artisans appear to have been very successful, each lecture having to be repeated on account of the demand for tickets. It is interesting to notice that the chairman of the Academic Board reports that "the presence of ladies in the classes stimulates manly qualities in the students, and encourages gentlemanly behaviour." Besides prizes in all five languages taught, the ladies have distinguished themselves in physics this year. The fees for the evening classes have been diminished by one-half, being now threepence each lecture.

THE National Fish Culture Association have transferred another large consignment of whitefish fry to the lakes in the Isle of Mull in order to further their acclimatisation to the waters of this country. Hitherto many experiments have been tried in this direction, but with no success. The American Government are rendering valuable assistance in effecting their propagation and are watching the result of the endeavours now being made with keen interest.

THERE will shortly appear, published by the Clarendon Press, "The Flora of Oxfordshire," including the contiguous portion of Berkshire, by G. Claridge Druce, F.L.S., &c. Over half a century having elapsed since the publication of Walker's "Flora of Oxfordshire," the many changes in nomenclature, the subdivision of species, and the great advance in botanical knowledge, demand a new work on the subject. Mr. Alfred French long ago commenced one, and on his premature death, in 1879, his MSS. came into Mr. Druce's possession. At the request of the Director of the Botanical Department of the British Museum, he undertook its completion. The "Flora" is intended to be not only a catalogue of the county species, with their localities, but also a history of them, and of the botanists connected with the University and county. About 900 species and varieties, additional to those given in Walker and Sibthorp, will be enumerated, and something like 20,000 records have been made in visiting nearly every parish in the county. The comparative plant occurrences in the counties of Berks, Bucks, Warwick, Northampton, and Gloucestershire will be shown. Orders should be sent to Mr. G. C. Druce, 118, High Street, Oxford.

A "BEGINNERS' STAR ATLAS," by the Rev. T. E. Espin, with an introduction by Mr. J. A. Westwood Oliver, is in the press, and will be published shortly by Messrs. W. Swan Sonnenschein and Co.

IN a paper read before the Academy of Sciences of Berlin at a recent meeting, Dr. G. Hellmann continued a paper read previously on certain regularities in the states of the weather in successive seasons of the year. The author, from a long series

of observations, draws a conclusion contrary to the current belief—viz. that a mild summer follows a mild winter. He studied the warm summers of Berlin from the year 1719 in one particular aspect—that is to say, with special reference to the succeeding winters. He regards that summer as warm when the temperature in June, July, August, and September, or at least in three of those months, is above the normal. Fifty-two such summers occurred between 1719 and 1885. Unfortunately there were certain gaps in the observations which could not be filled up; but there was no break in the observations between 1755 and the present, in all 130 years of uninterrupted observation. During this period there were 45 warm summers, or a proportion of 1 : 2·89. But, as in the case of mild winters, there was no periodicity of three years. Thus after the hot summer of 1763 there was not another for 12 years, and at the beginning of the present century there were 19 successive years (1799–1817) without a single hot summer. But in the case of the summers, as in that of the winters, a certain grouping is observable. In the 52 warm summers, in 31 cases 2 hot summers followed each other in succession, "so that one may wager 596 to 404 that one hot summer will be succeeded by a second." The influence of a hot summer on the succeeding autumn and winter (October to February) is that of these months 2·82 were too warm. For the individual months, with the exception of November, the probabilities are about equal. Given a summer with July, August, and September hot, and a cold January, a warm December and February may be expected. As a general rule two warm winter months may be expected after a hot summer. But warm summers differ: they do not last the same length of time, they have not the same intensity; and these variations exercise an important influence on the succeeding winter months. The author then discusses the cold winters of Berlin and the respective probabilities of the succeeding months being cold. The results of the whole investigation he sums up in three propositions arranged and stated as follows:—(1) A $\left\{\frac{\text{moderately}}{\text{very}}\right\}$ mild winter will most probably be succeeded by a $\left\{\frac{\text{cool}}{\text{hot}}\right\}$ summer. (2) A $\left\{\frac{\text{moderately}}{\text{very}}\right\}$ hot summer will most probably be succeeded by a $\left\{\frac{\text{moderately mild}}{\text{cold}}\right\}$ winter. (3) A $\left\{\frac{\text{moderately}}{\text{very}}\right\}$ cold winter will most probably be succeeded by a $\left\{\frac{\text{cool}}{\text{cold}}\right\}$ summer.

THE additions to the Zoological Society's Gardens during the past week include a Suricate (*Suricata tetradactyla*) from South Africa, presented by Miss F. M. Savill; two Common Badgers (*Meles taxus*), British, presented by Lord Willoughby de Broke; a Common Marmoset (*Hapale jacchus*) from Brazil, presented by Miss Henderson; a Cereopsis Goose (*Cereopsis novæ-hollandiæ*), a Black Swan (*Cygnus atratus*) from Australia, presented by Mr. F. L. Frodsham; a Mealy Amazon (*Chrysotis farinosa*) from South America, presented by Mr. W. Hodder; two Alligators (*Alligator mississippiensis*) from the Mississippi, presented by Mr. Charles Ridley; an Alligator (*Alligator mississippiensis*) from the Mississippi, presented by Miss Helmlicher; a Red-tailed Amazon (*Chrysotis erythrura*) from Brazil, three Upland Geese (*Bernicla magellanica* ♂ ♂ ♂) from the Falkland Islands, three Wigeons (*Mareca penelope* ♂ ♂ ♂), European, purchased.

OUR ASTRONOMICAL COLUMN

OCCULTATION OF ALDEBARAN ON MAY 15.—The ephemerides do not take cognisance of occultations of the brighter stars, when near to the sun's place, nor indeed, as a rule, of occultations generally which occur whilst the sun is above the horizon of the place to which the calculations are adapted. In the *Monthly Notices* of the Royal Astronomical Society for 1868, is a note communicated by Mr. R. S. Dyer, drawing attention to an occultation of Aldebaran on May 15 of that year, when the star was little more than 8° distant from the sun, and suggesting that observation would be possible with a good equatorial, and, at any rate, would be worth trying as a matter of curiosity. It does not appear from the succeeding numbers of the *Monthly Notices* that the occultation in question was anywhere observed, but on May 15 in the present year one of the same star will take place when its distance from the sun is 14½°, and some observers may be induced to make an attempt to record the phenomenon. At the Royal Observatory, Greenwich, the star escapes occultation by 5′ to the north of England and in Scotland the times for the several observatories are as follow:—

	Disappearance G.M.T.	Angle	Reappearance G.M.T.
	h. m.		h. m.
Liverpool ...	2 50·0 ...	19 ...	3 57 ...
Stonyhurst ...	2 47·6 ...	24 ...	3 57 ...
Glasgow ...	2 39·6 ...	38 ...	3 [illegible] ...
Edinburgh ...	2 37·9 ...	39 ...	3 [illegible] ...
Dunecht ...	2 35·3 ...	45 ...	3 [illegible] ...

At Dublin the star disappears at 2h. 46·2m. G.M.T. and reappears at 3h. 1·0m.; angles 19° and 354° respectively, counted as usual in the *Nautical Almanac*.

VARIABLE STARS.—(1) Dr. Gould, in the *Uranometria Argentina*, enters into some detail with respect to the relative magnitudes of the bright stars in *Corvus*, to the discrepancies in estimating which Argelander first directed attention in the case of the "Bonn Observations." It was considered that the Cordoba observations "served to remove all doubt as to the variability, within moderate limits, of all four of these stars, thus explaining the apparently contradictory nature of former observations." On the other hand, Mr. E. F. Sawyer, of Cambridgeport, Mass., says he carefully observed the relative stars of Corvus during the years 1882–84, and found that certainly variable by nearly one magnitude, but that the other stars appear to be sensibly constant," and he thinks that the difficulty is thus solved. From Dr. Gould's remarks, however, there is room for doubt on this point.

(2) A minimum of R Leonis may be expected about May 8. The observations from 1840 to 1883 afford indications of the existence of a perturbation in the period.

THE DOUBLE-STAR γ EQUULEI.—The duplicity of this star was detected by Mr. G. Knott in 1867; his measures in that year give for 1867·543, position 276°·84, distance 2″·33; for the epoch 1877·728 Mr. Burnham found the position 276°·1, distance 2″·16. The annual proper motion of the principal star appears to be + 0·00278, in right ascension, and + 0·0 in declination, and if Mr. Knott's measures of 1867 are reduced to Mr. Burnham's epoch, with these values, they become—

Position 308°·0—Distance 3″·20,

differing so widely from the Chicago results as to be quite indicative of the binary character of the object.

ASTRONOMICAL PHENOMENA FOR THE WEEK, 1885, MAY 3–9

(FOR the reckoning of time the civil day, commencing at Greenwich mean midnight, counting the hours on to 24, is employed.)

At Greenwich on May 3

Sun rises, 4h. 30m.; souths, 11h. 56m. 42·0s.; sets, 7h. 23m.; decl. on meridian, 15° 48′ N.; Sidereal Time at midnight, 10h. 11m.

Moon (at Last Quarter on May 7) rises, 22h. 32m.*; souths, 3h. 0m.; sets, 7h. 27m.; decl. on meridian, 18° 8′ S.

Planet	Rises h. m.	Souths h. m.	Sets h. m.	Time of meridian passage
Mercury ...	4 17 ...	11 25 ...	18 33 ...	11 25·1
Venus ...	4 33 ...	11 56 ...	19 19 ...	11 56·1
Mars ...	3 59 ...	10 51 ...	17 43 ...	10 51·1
Jupiter ...	11 50 ...	19 7 ...	2 24* ...	19 7·1
Saturn ...	6 32 ...	14 39 ...	22 46 ...	14 39·1

* Indicates that the rising is that of the preceding last quarter morning, the following day.

Phenomena of Jupiter's Satellites are such as are visible at Greenwich.

aturn, May 3.—Outer major axis of outer ring = 38″·3; r minor axis of outer ring = 17″·4; southern surface visible. ay 4, 17h.—Venus in superior conjunction with the Sun.

GEOGRAPHICAL NOTES

HE Austrian African explorers, Prof. Frederick Paulitschke Dr. Dominik Kammel von Hardegger, have returned from expedition to Africa. They started from Trieste on ember 30, 1884, and chiefly explored the interior of the as country. The Austrian explorers have established orological stations at Harrar and Zeila, which will be ed after by the English Consuls Pitten and King. The ctions they have brought with them, filling several cases, constitute a very valuable addition to the Austrian Imperial eum.

r the January meeting of the Royal Swedish Geographical ety, Dr. F. Svenonius gave a very interesting account of his to certain remote parts of Swedish Lapland last summer. speaker could not accept the theory set forth by some orities that the word "Lapp" was derived from the Lappish or Finnish *lappi, i.e.* "end" or "finish," signifying the inants of the end of the European continent. He believed the word was derived from *luppa* or *lappak, i.e.* "cave" or ess," a name given by the Scandinavians to this race from abits of the Lapps in earlier times living or taking refuge ves or recesses. It was a common thing, even now, for s to take refuge in such places in bad weather, or ie night when travelling. Having referred to the remarkstructure which forms the dwelling of the Lapp, he pro:d to describe the mountains, glaciers, lakes, and waterfalls vedish Lapland. The mountains were more imposing seen the Swedish than the Norwegian side, as in the latter place were too close to the spectator. They were of two kinds, the lled "alpine" and so-called "grass" mountains. The former lofty and jagged, and the latter—the most common—low and led. The alpine mountains were composed of hornblende, o, and eklogite, and the grass mountains of schist impregwith chalk. The highest parts of Swedish Lapland were around the sources of the river Rapaädnos, the highest which, Sarjektjåkko, was once believed to be the highest ain in Sweden, and west of the Lake Pajtasjärvi, where are two lofty peaks, Kaskasatjåkko and Kebnekaisse. The st glaciers in Sweden were found within these parts, the r having been named the "ice-depôt of Lapland." He ated that about 180 square kilometres, or one-seventh of the area, were covered with "eternal" ice, the depth of which d several hundred feet. It was impossible to say whether apland glaciers were increasing or decreasing. Judging ier European glaciers, they should be decreasing very fast. act that the flora of Lapland was actually receding, which d in the opposite direction, and seemed to indicate a deation of the climate, he believed was due to the circumstance ie Lapland glaciers had an "heirloom from the Glacial still to get rid of. The lakes covered a vast portion of ad chiefly between the mountains and the so-called "forest-

The surface area of the lakes here was one-third of the of Swedish Lapland. But there were also many great n the alpine districts. Of the waterfalls the most imposing he Stora Sjöfall, 130 feet high, and Harsprånget, 70 feet and with a volume of water estimated at 500 cubic metres cond. There were besides several beautiful but smaller n the Gellivara Lappmark. In conclusion, Prof. von , who has travelled much in Lapland, stated that he d that the word "Lapp" was derived from the old h word *lappaa, i.e.* "roam about," as suggested by a authority, viz. Prof. Friis, Professor of Lappish at the ania University.

DO CORA'S *Cosmos* for 1884 (vol. viii.) contains an ate paper on Tahiti and the natives of Polynesia, recently by Dr. Filippo Rho of the Italian Royal Marine, who sailed from Callao for the Pacific waters on board the *Caracciolo* in June, 1883. The "Kanaka," or Polynesian race proper, is described as presenting many points of resemblance to the Malays, from whom the writer supposes them to have originally sprung. But the type can be best studied in Tahiti and the other eastern islands of the Pacific, where it is found in its purest state and least affected by Papuan elements. It is subdolichocephalic, with cephalic index 76·2; keel-shaped skull; mesorrhine nose (index 49·3); not prognathous if unmixed, although in Tahiti the facial index is 75·0, and in general conformation not far removed from the white or European type. The nose, sometimes straight, sometimes aquiline, sometimes rather short and flat, is always characterised by wide nostrils. The jaw-bones, though strong, are not prominent; face oval; eyes black, well shaped, never oblique; complexion variable from light brown or copper to olive yellow, but always fairer than that of the Malays; hair black, often coarse, generally straight, but sometimes wavy; beard scant; stature very tall and slim, although a tendency is shown here and there towards obesity. The Tahitians are of a cheerful temperament, passionately fond of song and dance, and some favourable specimens are given of their *himenè*, a term derived from the English word "hymn," a relic of the days of the Protestant missionaries before the French occupation. These *himenè* are chiefly historical, religious, warlike, or amatory, the latter often extremely pathetic, as, for instance, the elegy of the distressed maid, who flies to the woods, crowns herself like Ophelia with flowers, and dies with the name of her faithless lover on her lips. "I turn weeping from side to side of my grassy couch; alas! he is away! we are severed for ever, and I alone keep my love. I stand in the shade of the Tu tree, and wreathe myself in the flowers he loved, to bear the grief of my beloved who has forsaken me. Thou forsakest me, never to return, and I die alone like the bird that finds no branch of any tree whereon to perch." There is an amusing description of Queen Marau's visit to the Italian man-of-war, whose officers were afterwards invited to a banquet, the *menu* of which is given in Tahitian and Italian. It began with roast pork, followed by raw fish *à la taiero* (a kind of pickle made of grated coco, sliced lemons, and salt water kept in a bamboo cane), prawns, salt fish, bananas, taro, a species of mango (*Spondias dulcis*), concluding with a dessert of cocoa-nuts and oranges. A native banquet is thus a sort of *résumé* of the fauna and flora of the Society Islands.

THE *Bollettino* of the Italian Geographical Society for April publishes two interesting letters from the engineer, Count Augusto Salimbeni, who had accompanied the third Bianchi expedition to Gojam, which had such a disastrous termination. These letters, addressed to Sig. Grimaldi, Minister of Agriculture, and to Prof. Tacchini, are dated from Dildil-Jimma, Gojam, December 27, 1884, and January 2, 1885, and describe the commencement of a stone bridge over the River Temcha, the first of the kind in the country since that thrown some two centuries ago across the Abai (Upper Blue Nile) by the Portuguese. This work, so far carried out under great difficulties with the assistance of Giuseppe Andreoni from the Swiss Canton of Ticino, will consist of three arches with a total length of 50 m. and 20 m. above the stream. King Tekla-Haimanot, at whose request it was undertaken, was greatly surprised at the progress already made, and expressed his satisfaction to Count Salimbeni in these terms:—"At first I did not believe you. But it was not altogether my fault. Europeans coming here have talked to me about the splendours of their lands, have brought me handsome presents, but have never shown me any of their works in stone and mortar. Our history relates how the Portuguese, to build the bridge over the Abai, brought down fire from heaven, with which they dammed up the water. It is also said that they required a thousand oxen daily to mix the mortar. But you have asked for nothing but stones, sand, wood, and water. Your work is better than that of the Portuguese. Now I believe you." It was expected that the bridge would be finished in March.

THE same number of the *Bollettino* brings to a conclusion the important and timely paper by L. Paladini on the foundation of European colonies in Africa, and especially in Algeria and Tunis. The object of the writer is to warn Italy against rash enterprises of this sort, nearly all of which have hitherto proved to be financial and even political failures. Speaking more particularly of Algeria, he describes the results, after fifty-four years of occupation, as almost nothing compared with the vas

expenditure of blood and treasure incurred by the French Government. The military expenditure alone, he calculates, at about a year's average of 3,000,000*l.*, or 162,000,000*l.* to the present time. To this have to be added nearly 4,000,000*l.* for some eighty fortresses and stations of all sorts required to overawe the natives; about 1,800,000*l.* yearly for the civil administration; 8,000,000*l.* for caravanserais to develop the trade of the interior; 6,000,000*l.* for the ports of Bona, Philippeville, Algiers, Bougie, Oran, and one or two others; 8,000,000*l.* or 10,000,000*l.* for arsenals, canals, dredgings, and other hydraulic works, besides many other incidental expenses, the whole far exceeding any profits hitherto realised by the trade of the country. The writer dwells upon the rivalries and heartburnings that have sprung up between the military and civil sections of the European community, which hate each other almost more intensely than both are detested by the natives. He shows that even agriculture has yielded no returns at all commensurate with the outlay incurred, and concludes that, if not actually insoluble, the problem how to found useful and profitable colonies in Africa will always remain one of the most difficult questions for the statesman and political economist.

THE *Boletin* of the Madrid Geographical Society for February gives a complete list of the recent acquisitions of Spain in West Africa. These comprise the west coast of the Sahara between Cape Bogador (29° 9′ N.) and Cape Blanco (20° 45′ N.), both included; in the gulf of Guinea, the coast-line stretching from the Muni River, forming the northern limit of the French possessions on the Gaboon, northwards to the Rio Campo (0° 43′ to 2° 41′ N.). On the Sahara coast six stations have already been established, and all points giving access to shipping will be permanently occupied. The old treaties with the chiefs on the Rio Benito have also been renewed, with a view to prevent the threatened advance of the French in that direction.

PROF. ESCRICHE, of Quadalajara, recently described, before a conference at Madrid, his project for "geographical parks." The geographical park is a public garden, reproducing on a certain scale, according to its extent, the geographical features of a country. If it is a kind of map in relief; the principal towns would be represented by places surrounded by trees, the main ways of communication by winding paths; a succession of hillocks would act for the ranges of mountains, streams of water for the rivers. The clumps of trees within the network of roads would form varied pastures, in which the natural products of each locality would find its place among the flowers, and in the centre, where the town should be, would be placed small structures, in which would be photographic views of the principal monuments, but especially the most important astronomical, geographical, historical, and artistic information with regard to the town represented.

BEFORE the last meeting of the Verein für Erdkunde, at Halle, Dr. Alfred Hettner described the United States of Columbia, their characteristics, and present condition, based on recent journeys there. After deducting the disputed territory on its borders, Columbia is half as large again as the German Empire. Its main geographical divisions are the isthmus region, the mountainous districts in the west belonging to the Andes system, and the low-lying plains of the Amazon and the Orinoco in the east. To the last belongs the Meta, which is very suitable for navigation, but is little used for that purpose; while the Magdalena, which is navigable for 640 kilometres to the Honda Cataract, belongs to the first division. The forest region, with palms in the lower and tree-ferns in the upper parts, extends up to 2900 m., the snow-line being 4600 m. in height. The Indian population, amongst which the Muysca (Tschibtscha) rank only behind the Incas and Aztecs in civilisation, was estimated in the sixteenth century at ten millions, but are said to have been reduced by the Spaniards to one-fiftieth of that number. The whole population now is given at three millions, and, according to the estimates of the Columbians themselves, 10 per cent. of these are whites, 40 Mestizos, 35 Indians, and 15 Negroes. Trade is hampered by the bad condition of the roads. Gold, silver, coffee, and hides are the chief articles of export. Railway construction, like trade, is prevented by natural difficulties and the indolent, unpractical nature of the people.

THE *Mittheilungen* of the Vienna Geographical Society for March (Band xxviii. No. 3) contains papers on the movements of the Dachstein glacier during the period 1840-84, by Dr. Simony; an account of the latest explorations in Eastern Equatorial Africa, by Dr. Le Monnier; and the first part of a paper on the geographical work of the German Government in Hamburg, by Prof. Gedeyth. At the meeting held on 24 Dr. Lenz read a paper on the German colonies in East Africa and Oceania, which is not printed as yet.

THE Norwegian Government have decided to send an expedition this summer to Finmarken, in the gasboat [illegible] for the purpose of effecting hydrographic researches and soundings along the coast. The cost is estimated at 10,000*l.* The Swedish Government grant for this year to recruit the publications amounts to about 700*l.* A sum of 50*l.* has been contributed towards the expenses of Mr. G. [illegible] algological researches in England and Scotland this summer.

FURTHER NOTES ON THE GEOLOGY OF PALESTINE, WITH A CONSIDERATION OF THE JORDAN VALLEY SCHEME.[*]

THE subject was divided as follows:—(I.) The [illegible] Formations of Palestine and Egypt; (II.) The [illegible] Arabah and the Dead Sea Basin; (III.) The Jordan Valley Canal Scheme.

Since the date of the previous communications to Nature, 1882, much attention had been directed to the geological structure of Palestine and the adjacent regions, especially Egypt. Besides the discussions in the pages of Nature on the suggested Jordan Valley canal, an important expedition was sent out by the Palestine Exploration Fund during the years 1883-84, whilst about the same time Sir J. W. Dawson visited Egypt, Suez, the Lebanon, &c., and gave his results in the *Geological Magazine*. Important information relative to the Libyan Desert has lately been published by Prof. Zittel in his "Palæontographica."

I. (*a*) *Schists, Gneiss, Granite, and Porphyrs.*—These are described the relations of the crystalline rocks and Nubian sandstone at the First Cataract (Assouan-Syene). A lower granitoid gneiss, which he refers to the Laurentian, penetrated by intrusive granite and diorite, is covered in almost horizontal strata by a second crystalline series consisting mainly of porphyries, traversed by dykes of felsite and basalt. Incidentally it was mentioned that, according to Russegger's map, all the Nile valley [illegible] where the river is passing over such crystalline rocks, while the more tranquil stretches of water belong to the soft Cretaceous Nubian sandstone. An immense mass of crystalline rocks underlies all at the great bend of the Nile which has Abu Hamed at its apex: the axis of this system occurs in the Monastir Mountains, which is the wildest region between Assouan and Berber. Dr. Dawson thinks that the porphyries of Mount Hor may be referred to his second series of rocks, which, in more northern regions, is represented by the Arvonian and Huronian.

(*b*) "*The Nubian Sandstone.*"—This extensive series of the rocks between the Crystallines and the Upper Cretaceous may be resolved into three sections of different geological age. The Carboniferous age of the lower sandstone and limestone of Wady Nasb has been known in several places since the discoveries of Mr. Holland; but Prof. Hull first traced this section up the Arabah, and almost as far as the Dead Sea. The middle division is Cenomanian; it is probably the main the original Nubian sandstone of Russegger, and extended in Egypt, occurs in great force at Farâfra, and constitutes the cliffs on the east side of the Dead Sea. Thereupon the Lebanon division of the *set-diana* Nubian sandstone, which in all probability is really newer than either of the above, as well up amongst the Cretaceous limestones, and possibly on the horizon of certain lignitiferous rocks occurring at Esneh on the Nile.

(*c*) *Cretaceous and Nummulitic Limestone.*—The Cretaceous beds are the most important factors in Syria, which as a part of Eocene age are much the thickest. Sir J. W. Dawson's section of Jebel Attâli all (partly after Le Vallassor) shows that the systems are faulted together. He considers the [illegible] shores of the Gulf of Suez an important one as proving [illegible] intermediate; have in both systems, thus linking the [illegible] the African types. The Cretaceous beds in Egypt are [illegible] less calcareous than in Palestine; an abundance of [illegible] gypsum, and bituminous is noted on certain horizons. This last circumstance is noteworthy, for it will be remembered

[*] Abstract of paper read at the meeting of the Geologists' [illegible] Friday, March 6, by W. H. Hudleston, M.A., F.R.S., F.G.S.

Further proof was obtained of the independent character of the basin north of the watershed in marl deposits at an elevation of 1400 feet above the present Dead Sea level; these contain species of *Melania* and *Melanopsis* identical with some of those now existing in the fresh portions of the Jordanic basin. Hence there is little doubt that we must carry the successive lakes mentioned by Capt. Conder some stages higher than had been supposed previously. It was noted also, as bearing on this subject, that the old marls of the Jordanic lakes are not so unfossiliferous as M. Lartet would lead us to suppose. Tristram describes one species of *Melania* and two of *Melanopsis* as abundant in a semi-fossil condition in several of these old marl deposits.

Next comes the consideration of a problem which results from the adoption of the independent lake-basin theory—viz. "Since the Dead Sea has no outlet, what has become of the materials that have disappeared?" Seeing that the lateral wadies are, in the main, gorges of erosion, the difficulty is still further enhanced. That there has been some connection in past time between this curious hollow and the volcanic outbursts of the Jaulan, &c., is not improbable; indeed, it has long been suspected that an explanation of the phenomenon might, in part at least, be found in this direction. There is a partially analogous case in the meridional trough with its string of charming lakes, some fresh and some salt, which, Mr. Thompson tells us, extends along the west side of the old East African volcano, Mount Kenia: the fresh-water lake, Baringo, 3200 feet above sea-level, occupies the lowest depression of this great hollow.

III. *The suggested Jordan Valley Canal.*—The remainder of the paper was occupied in considering the northern section, by which the waters of the Mediterranean are to be admitted into the Jordanic basin, so as to convert it into an inland sea. If taken through the Vale of Esdraelon into the valley of the Jâlud (Jezreel), between Little Hermon and the Gilboa range, the length would be about 25 miles, starting from the port of Haifa under Mount Carmel. The height of land is 285 feet, and the mean depth of the cutting to the water-surface would be about 150 feet, without including the depth of the canal itself. The surface of the Vale of Esdraelon consists mainly of Post-Tertiary loams, &c., below which hard limestone, and possibly basalt, would have to be encountered. The alternative of a railway was discussed.

CHINESE INSECT-WHITE WAX

A PARLIAMENTARY paper which has recently been published (China, No. 2, 1885) contains a report of a journey through Central Sze-chu'an, which was made by Mr. Hosie, consular agent at Chung-king, chiefly for the purpose of collecting information on the subject of insect white wax, specimens of the insect wax-trees, and forms of the wax product, at the request of Sir Joseph Hooker. The report describes the country traversed, its trade and trading capabilities, and such information as was attainable on any commercial product of the district; but the portion relating to insect white wax is the most interesting part of the paper.

"Insect tree" is the name given by the Chinese in the extreme west of Sze-chu'an to what is probably the *Ligustrum lucidum* of botanists. The point will doubtless be decided at Kew by the specimens which Mr. Hosie has sent home. It is also called the winter-green or evergreen tree; while in the east of the province it is known as the "crackling flea tree," owing, it is said, to the sputtering of the wood when burned. It is an evergreen, with leaves which spring in pairs from the branches. They are thick, dark green, glossy, ovate, and pointed. In the end of May or beginning of June the tree bears clusters of small white flowers, which give place to small seeds of a dark blue colour. In the month of May, 1883, Mr. Hosie found attached to the bark of the boughs and twigs numerous brown pea-shaped excrescences or galls, in various stages of development. In the earlier stages they looked like minute univalves clinging to the bark. The larger galls were readily detachable, and, when opened, presented either a whitey-brown pulpy mass, or a crowd of minute animals, whose movements were only just perceptible to the naked eye. Last year an opportunity of examining these galls and their contents with some minuteness in the chief wax-producing locality in the province presented itself. They are very brittle, and there was found, on opening them, a swarm of brown creatures, like minute lice, each with six legs and a pair of club *antennæ*, crawling about. The great majority of the galls also contained either 1 small

white bag or cocoon, containing a chrysalis, whose movements were visible through the thin covering, or a small black beetle. This beetle also has six legs, and is provided with a long proboscis, armed with a pair of pincers. It is called by the Chinese the "buffalo," probably from its ungainly appearance. After a few days it turned out that each chrysalis developed into a black beetle, or "buffalo." If left undisturbed in the broken gall, the beetle will, heedless of the wax insects, which begin to crawl outside and inside the gall, continue to burrow with his proboscis and pincers in the inner lining of the gall, which is apparently his food. The Chinese believe that he eats his minute companions in the gall, or at any rate injures them with the pressure of his heavy body, and galls in which beetles are numerous sell cheaper than others. But careful investigation showed that the beetle does not eat the other insects, and that his purpose within the gall is a more useful one. When a gall is plucked from the insect tree an orifice is disclosed where it was attached to the bark. By this the wax insects escape. But if the gall remained attached to the tree no mode of escape would appear to be provided for them. The beetle provides this mode. With his pincers he gradually bores a hole in the covering of the gall, which is of sufficient size to allow him to escape from his imprisonment, and which allows egress at the same time to the wax insects. When the beetles were removed from the galls some of them made efforts to fly; but at that time their *elytræ* were not sufficiently developed, and they had to content themselves with crawling, a movement which, owing to the long proboscis, they performed very clumsily. Through the orifice thus created by the beetle the insects escape to the branches of the tree, if the gall be not plucked soon enough. When plucked, the galls are carried in headlong flight by bearers who travel through the night for coolness to the market towns, and every endeavour is made to preserve a cool temperature in order that the heat may not force the insects to escape from the galls during the journey.

The wax-tree is usually a stump, varying from three or four to a dozen feet in height, with numerous sprouts or branches rising from the gnarled top of the stem. The leaves spring in pairs from the branches. They are light green, ovate, pointed, serrated, and deciduous. The branches are rarely found more than six feet in length, as those on which the wax is produced are cut from the stems with it. The sprouts of one and two years' growth are too pliant, and it is only in the third year, when they are again sufficiently strong to resist the wind, that wax insects are placed on them. In June some of the trees bear bunches apparently of seeds in small pods, and specimens of these have been sent to Kew.

The wax insects are transferred to these trees about the beginning of May. They are made into small packets of twenty or thirty galls, which are inclosed in a leaf of the wood-oil tree, the edges of which are fastened together with rice-straw. These small packets are then suspended close to the branches under which they hang. A few rough holes are made in the leaf by means of a large needle, so that the insects may find their way through them to the branches. On emerging from the galls the insects creep rapidly up the branches to the leaves, where they remain for thirteen days, until their mouths and limbs are strong. During this period they are said to moult, casting off "a hairy garment," which has grown in this short time. They then descend to the tender branches, on the under sides of which they fix themselves to the bark by their mouths. Gradually the upper surfaces of the branches are also dotted with the insects. They are said not to move from the spots to which they attach themselves. The Chinese idea is that they live on dew, and that the wax perspires from the bodies of the insects. The specimens of the branches encrusted with wax show that the insects construct a series of galleries stretching from the bark to the outer surface of the wax. At an early stage of wax production an insect called by the Chinese the "wax-dog" is developed. Mr. Hosie was unable to obtain a specimen of this insect, but it was described to him as a caterpillar, in size and appearance like a brown bean. His theory (which, he confesses, is unsupported by outside evidence) is that the female of the "buffalo" beetle, already mentioned, deposits eggs on the boughs of the insect tree or the wax tree, as the case may be, and that the "wax-dog" is the offspring of the buffalo. There may possibly be a connection between this caterpillar and the gall containing the wax insects. It is said that during the night and early morning the insects relax their hold of the bark, and that during the heat of the day they again take firm hold of it. The owners of trees are in the habit, during the first month of the season, of beating the trees with thick clubs to shake off the "wax-dog," which, they assert, destroys the wax insects. After the first appearance of the branches are coated with wax, and the "wax-dog" is subsequently unable to reach his prey. The first appearance of the wax in the boughs and twigs has been likened to a white sulphate of quinine. This gradually becomes darker, and after a period of from ninety to a hundred days, the good years has attained a thickness of about a quarter of an inch. When the wax is ready, the branches are lopped, and as much of the wax as possible is removed by hand. The placed in an iron pot with water, and the wax, rising to the surface at melting-point, is skimmed off and placed in moulds, whence it emerges as the white wax of commerce. The wax which cannot be removed by hand is placed with the in a pot with water, and the same process is gone through. The latter is less white and of an inferior quality. The Chinese, with their usual carefulness that nothing be lost or wasted, boil the insects, which have meantime sunk to the bottom of the pot, and, placing them in a bag, squeeze them until they have given up the last drop of the wax. They finish up their industrious existence by being thrown to the pigs. They enter in the manufacture of candles. It melts at 160° F., while the wax melts at about 95°. In See-chu'an it is mixed with other waxes to give the latter greater consistency, and candles, when cold, are dipped in melted white wax to give them a harder coat, and to prevent the tallow from running over when they are lighted.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

CAMBRIDGE.—The following courses of lectures are being demonstrations are being given this term:—

Physiology, Elementary, by Prof. Foster; Physiology, Circulation and Respiration, Dr. Gaskell; Central Nervous System, Mr. Langley; Chemical Physiology, Mr. Lea; Preparation Class for 2nd M.B., Mr. Hill.

Elementary Biology, Mr. Sedgwick; Anatomical Distinction of the Races of Mankind, Prof. Macalister; Demonstrations in Topographical Anatomy of the Head and Neck, Prof. Macalister.

Morphology and Entomology of Vertebrata, Mr. Sedgwick; Elementary Osteology and Advanced Course on Animal Morphology, Mr. Harmer; Morphology of Vertebrata, Mr. Willey; Development of Limbs of Vertebrata, Mr. Gadow.

Elementary Botany, Prof. Babington; Morphology of Phanerogams, with practical work, Elementary and Advanced Courses, Dr. Vines; Demonstrations in Systematic Botany, Mr. Hemsley; Morphology of the Flower, Mr. Hicks; Physiological Botany, with Demonstrations, Mr. F. Darwin.

Geology, Local Stratigraphy, Prof. Hughes; Stratigraphical Rules, Mr. Hill; Principles, Dynamical and Structural, Mr. Roberts; Irregular Accumulations of Doubtful Age, Mr. Marr; Palæontology, Wm. T. Roberts; Mineralogy and Petrology, Mr. Harker; Field Lectures, Prof. Hughes; Palæontology of Reptiles and Birds, Mr. Gadow.

Chemistry, General Equilibrium and the Dissociation of Gases, Prof. Liveing; Organic Chemistry, Mr. Main; Chemical Course, Mr. Pattison Muir; Course for Beginners; Gas Analysis, Jacksonian Assistant; Elementary Physical Chemistry, Mr. Heycock; Demonstrations, Mr. Neville, Mr. Fenton, Mr. Neville.

Physics: Optics, Prof. Stokes; Prof. Thomson; Kinetic Theory of Gases; Elementary and Advanced Courses, Mr. Glazebrook and Mr. Glazebrook; Elementary Physics, Mr. Hicks; Demonstrations, Mr. Shaw and Mr. Glazebrook.

Mineralogy, Prof. Lewis; Demonstration Course, Mr. Hutchinson.

Machine Construction, Mr. Lyon; Surveying, Dr. Glazebrook; of Mechanism.

Advanced Mathematical Lectures open to the Examination, Waves, Mr. Glazebrook; Elastic Solids, Mr. Love; Higher Geometry, Mr. Ball; Analysis, Dr. Besant; Laplace's and Bessel's Functions, Mr. Pendlebury; Calculus of Variations, Mr. H. M. Taylor; Rigid Dynamics, Mr. Webb.

SOCIETIES AND ACADEMIES

LONDON

yal Society, April 16.—"Note on an Experiment by lni." By Charles Tomlinson, F.R.S.

rd Rayleigh, in a memoir "On the Circulation of Air in t's Tubes," &c., remarks (*Phil. Trans.*, 1884, part 1, p. 1) "it was discovered by Savart that very fine powder does ollect itself at the nodal lines, as does sand in the produc- of Chladni's figures, but gathers itself into a cloud, which, hovering for a time, settles itself over the places of maxi- vibration.

Savart's memoir, "Sur les Vibrations Normales" (*An. de t de Ph.* for 1827, xxxvi. 187), the author distinctly claims ove-named discovery. At p. 190 he refers to the nodal of Chladni, but adds that by mixing with the sand a finer such as lycopodium, "la poussière fine se réunit pour r d'autre lignes circulaires que ce physicien n'a pas connues,"

raday, in his critical examination of Savart's memoir (*Phil. ts.*, 1831, p. 299) apparently takes it for granted that rt started with an original observation.

it this interesting discovery, which has been so fruitful in tiful results, is really due to Chladni. In his "Traité oustique," Paris, 1809, he remarks, p. 125:—"Si un peu oussière fine est mêlée au sable, elle pourra mieux servir faire voir aussi les centres des vibrations, c'est-à-dire, les oits où les parties vibrantes font les plus grandes excursions : olécules les plus petites de la poussière s'accumuleront sur ndroits."

ladni is even more explicit in his "Neue Beyträge zur stic" (4to, Leipzig, 1817). At p. 7 he recommends "etwas *is lycopodii*" as the fine dust to be mixed with the sand; at p. 69 he remarks that when fine dust accumulates on the es of vibration, it is in heaps more or less round or long, according to the form assumed by the vibrating part.

hen Wheatstone reproduced Chladni's figures on square s (*Phil. Trans.*, 1833, p. 593) he did not notice the re- able figures produced by mixing a fine powder with the . This was the less necessary because Faraday's memoir been so recently published, and its conclusion was so satis- ory, namely, that when a plate is vibrating, currents are olished in the air lying upon the surface of the plate, which from the nodal lines towards the centres of maximum ation, and then, proceeding outwards from the plate to a ter or less distance, return towards the nodal lines.

ith the exception of a very few elementary specimens on a l scale, as given by Chladni and Faraday, this class of es has been neglected by writers on physics. The author gives directions for the production of these figures when and lycopodium, flowers of sulphur, &c., are used, and in ding sheet twenty-one are represented of plates of various erial and form.

pril 16.—"On the General Characters of *Cymbulia*." By n D. Macdonald, R.N., M.D., F.R.S.

he Pteropoda being so purely pelagic in their habit place out of the reach of zoologists in general; and even sys- atic writers, as in other cases, are often misguided by in- ect figures and descriptions made up probably from scanty lefective data, but which have, nevertheless, been handed n to us with a show of truth.

he author was impressed with the idea that the figures and riptions of the species of *Cymbulia* extant were not reliable; having had an opportunity of examining some specimens n in the Indian Ocean, he found that such was really the . In the natural position of the animal the toe of the line slipper of *Cymbulia* should be taken as posterior, and broadly-notched heel as anterior. Both animal and shell reversed in Mr. Adams's figure of *Cymbulia proboscidea*, but is, after all, an error of less importance than that in De nville's figure, in which, although the shell is represented ts proper position, the animal is reversed. A pair of eyes also given in a position where ears alone would be possible, e there is no more evidence of the existence of eyes in than in any other genus of Pteropods. The notion [redacted] connecting lobe between the fins is a mistake, [redacted] connected above and behind so as to

[redacted]r.—Prof. W. H. Flower, [redacted] chair.—Mr. Sclater ex-

hibited and remarked on a pair of pheasants from Bala Murghab, Northern Afghanistan, belonging to H.R.H. the Prince of Wales.—Mr. G. E. Dobson, F.R.S., exhibited some skulls of *Crocidura aranea*, and pointed out that they possessed supernumerary teeth (premolars) in the upper jaw.—The Secretary exhibited, on behalf of M. George Claraz, an egg of Darwin's Rhea; and read some notes by M. Claraz on the habits and distribution of this Rhea.—Mr. G. A. Boulenger exhibited a specimen of a Brazilian Snake which had partly swallowed an Amphisbænoid Lizard. The lizard had in its turn partly eaten its way out through the body of the snake.—A communication was read from Sir Richard Owen, K.C.B., containing remarks on the structure of the heart in *Ornithorhynchus* and in *Apteryx*.—Mr. Oldfield Thomas read a paper on the characters of the different forms of the *Echidna* of Australia, Tasmania, and New Guinea, all of which he was inclined to refer to one varying species.—Dr. St. George Mivart, F.R.S., read a memoir on the anatomy, classification, and distribution of the Arctoidean Carnivorous Mammals. The author, after briefly noticing the papers of other naturalists who have of late years treated of this subject, described the main facts concerning the anatomy of the various Arctoid genera, especially as regards their osteology and dentition, and gave detailed comparisons of the proportions of the various parts of the skeleton, comparing them with those of the Æluroids and Cynoids.—Dr. F. H. H. Guillemard, F.Z.S., read the second part of his report on the collection of birds made during the voyage of the yacht *Marchesa*. The present paper gave an account of the birds collected in Borneo. It also contained notes on some birds obtained on the island of Cagayan Sulu, on the north-east coast of Borneo.

Royal Microscopical Society, April 8.—The Rev. Dr. Dallinger, F.R.S., President, in the chair.—Mr. Crisp exhibited a model of an old microscope described in an Italian work published in 1686.—Mr. H. G. Madan exhibited and described Bertrand's polarising prism. He also exhibited a modification of Ahren's double-image prism.—Mr. Dowdeswell exhibited some septic microbes from high altitudes, and detailed experiments as to bacterial germs found at various heights, notably upon the Neisen, at an elevation of about 7500 feet.—Mr. A. D. Michael gave a summary of his paper on "New British Oribatidæ." He first called attention to the nymph of *Cepheus bifidatus*, which he had just discovered; the species is very rare, and the immature stages were not known. Last September, at Keswick, Mr. Michael found two or three specimens, and instead of preserving them as examples, determined to try and breed from them. He isolated them, and after some weeks obtained a few eggs, from which he reared four larvæ; these he has carefully watched for six months until they had changed to nymphs and become full grown; he then killed and preserved two specimens of the hitherto unknown nymph, reserving the two others to rear to the imaginal condition. One was lost just before the final change, the other lived. The nymph which was exhibited was a very remarkable and beautiful creature, surrounded with concentric rows of curved serrated spines longer than the body. Mr. Michael then called attention to a new species of *Hypochthonius*, proposed to be called *H. lanatus*. The abdomen is segmented, and the segments are to a certain extent retractile, as in many insects; this enables the creature to erect or lower the long spines attached to the edges of the segments at will.—An interesting new species, to be called *Notaspis serratus*, abundantly provided with long serrated hairs, and a curious nymph of a *Damæus*, to be called *D. lanupes*, which carries its cast dorsal skins in a pyramid on its back, like a pile of dish covers, and has a central projection on each skin, forming a column to support the whole, were also shown and described, besides other new species.—Mr. Crisp called attention to some very interesting experiments by Dr. Nussbaum and Dr. Gruber, on the artificial division of infusoria. Dr. Nussbaum divided an *Oxytricha* into two halves, either longitudinally or transversely, and found the edges at the point of division were soon surrounded with new cilia. Dr. Gruber artificially divided *Stenter cæruleus* with similar results.—Mr. C. H. Kain's letter on the use of balsam of Tolu was read.—Mr. H. Mills's note on the filamentous projections on the margin of the diatom (*Stephanodiscus niagaræ*) was read, and slides in illustration were exhibited.—Mr. G. C. Karop remarked on an examination he had recently made of the saliva in a case of hydrophobia. The specimens presented the following characters.—Epithelium in large masses, most of the cells crowded with micrococci; bacilli of various lengths, and very variable in diameter. A few showed evidence

S. N. STOUT.

In Casks, 12/6 per 9 gals. In Bottle, 3/3 per doz. Impl. Pts.*

* Bottles charged 6d. per doz., and allowed at the same rate if returned; but they must be paid for with the liquor.

Neither sugar, saccharum, nor any of the many new Brewing Materials are used in the manufacture of the "S. N." Stout; it is Brewed entirely from the finest Malt and Hops; it is, too, more hopped than Stout is generally; therefore, besides being very nutritious, it is an excellent Tonic and particularly suited for Invalids, ladies nursing, or anyone requiring a good strengthening beverage. It is a "Sound Nutritious" Tonic, and very much recommended by Medical men.

BEST BLACK INK KNOWN.

DRAPER'S INK (DICHROIC).

DIFFERING FROM ANYTHING ELSE EVER PRODUCED.

Writing becomes a pleasure when this Ink is used. It has been adopted by the principal Banks, Public Offices, and Railway Companies throughout Ireland.

It writes almost instantly Full Black. Flows easily from the Pen.
Does not corrode Steel Pens. Blotting-paper may be applied at the moment of writing.
Is cleanly to use, and not liable to Blot.

Can be obtained in London, through Messrs. Barclay & Sons, Farringdon Street; W. Edwards, Old Change; F. Newbery & Sons, Newgate Street; J. Austin & Co., Duke Street, Liverpool; and to be had of all Stationers.

BEWLEY & DRAPER (Limited), Dublin.

WAY'S PILLS THIS MEDICINE

re for all Disorders of the LIVER, STOMACH
. A Great PURIFIER of the BLOOD; a
ructor of the System, in cases of WEAKNESS
Y, and is unequalled in Female Complaints.

THE CELEBRATED

Is unrivalled for Gardeners', Foresters', Farmers', Joiners', and Amateurs' use. It requires no oil. Sharpen with a spittle or water. Puts on a keen, sharp edge; no turning about this. Has stood the test of ten years. Out in Hones for Axes, Hedge Knives, Razors, Penknives, and Plane Irons, &c. Honourable Mention, Paris Exhibition, 1878; and Bronze Medal, London International Exhibition, 1884. Ask your Ironmonger or other retail house to get you one, and give my address; if he won't, drop me a note.
